# Package 'pracma'

March 4, 2022

Water 4, 2022
Type Package
Version 2.3.8
<b>Date</b> 2022-02-19
Title Practical Numerical Math Functions
<b>Depends</b> R (>= $3.1.0$ )
Imports graphics, grDevices, stats, utils
Suggests NlcOptim, quadprog
<b>Description</b> Provides a large number of functions from numerical analysis and linear algebra, numerical optimization, differential equations, time series, plus some well-known special mathematical functions.  Uses 'MATLAB' function names where appropriate to simplify porting.
License GPL (>= 3)
ByteCompile true
LazyData yes

# Description

This package provides R implementations of more advanced functions in numerical analysis, with a special view on on optimization and time series routines. Uses Matlab/Octave function names where appropriate to simplify porting.

Some of these implementations are the result of courses on Scientific Computing ("Wissenschaftliches Rechnen") and are mostly intended to demonstrate how to implement certain algorithms in R/S. Others are implementations of algorithms found in textbooks.

#### **Details**

The package encompasses functions from all areas of numerical analysis, for example:

- Root finding and minimization of univariate functions, e.g. Newton-Raphson, Brent-Dekker, Fibonacci or 'golden ratio' search.
- Handling polynomials, including roots and polynomial fitting, e.g. Laguerre's and Muller's methods.
- Interpolation and function approximation, barycentric Lagrange interpolation, Pade and rational interpolation, Chebyshev or trigonometric approximation.
- Some special functions,
   e.g. Fresnel integrals, Riemann's Zeta or the complex Gamma function, and Lambert's W computed iteratively through Newton's method.
- Special matrices, e.g. Hankel, Rosser, Wilkinson
- Numerical differentiation and integration,
   Richardson approach and "complex step" derivatives, adaptive Simpson and Lobatto integration and adaptive Gauss-Kronrod quadrature.

pracma-package 9

Solvers for ordinary differential equations and systems,
 Euler-Heun, classical Runge-Kutta, ode23, or predictor-corrector method such as the Adams-Bashford-Moulton.

- Some functions from number theory, such as primes and prime factorization, extended Euclidean algorithm.
- Sorting routines, e.g. recursive quickstep.
- Several functions for string manipulation and regular search, all wrapped and named similar to their Matlab analogues.

It serves three main goals:

- Collecting R scripts that can be demonstrated in courses on 'Numerical Analysis' or 'Scientific Computing' using R/S as the chosen programming language.
- Wrapping functions with appropriate Matlab names to simplify porting programs from Matlab or Octave to R.
- Providing an environment in which R can be used as a full-blown numerical computing system

Besides that, many of these functions could be called in R applications as they do not have comparable counterparts in other R packages (at least at this moment, as far as I know).

All referenced books have been utilized in one way or another. Web links have been provided where reasonable.

#### Note

The following 220 functions are emulations of correspondingly named Matlab functions and bear the same signature as their Matlab cousins if possible:

```
accumarray, acosd, acot, acotd, acoth, acsc, acscd, acsch, and, angle, ans,
arrayfun, asec, asecd, asech, asind, atand, atan2d,

gammainc, gcd, geomean, gmres, gradient,
hadamard, hankel, harmmean, hilb, histc, humps, hypot,
idivide, ifft, ifftshift, inpolygon, integral, integral2, integral3,
interp1, interp2, inv, isempty, isprime,
legendre, linprog, linspace, loglog, logm, logseq, logspace, lsqcurvefit,
lsqlin, lsqnonlin, lsqnonneg, lu,
magic,meshgrid,mkpp,mldivide,mod,mrdivide,
nchoosek,ndims,nextpow2,nnz,normest,nthroot,null,num2str,numel,
ode23,ode23s,ones,or,orth,
pascal, pchip, pdist, pdist2, peaks, perms, piecewise, pinv, plotyy,
```

10 pracma-package

```
pol2cart,polar,polyfit,polyint,polylog,polyval,pow2,ppval,
primes, psi, pwd,
quad, quad2d, quadgk, quad1, quadprog, quadv, quiver,
rad2deg,randi,randn,randsample,rat,rats,regexp,regexpi,
regexpreg,rem,repmat,roots,rosser,rot90,rref,runge,
sec, secd, sech, semilogx, semilogy, sinc, sind, size, sortrows, sph2cart,
sqrtm, squareform, std, str2num, strcat, strcmp, strcmpi,
strfind, strfindi, strjust, subspace,
tand, tic, toc, trapz, tril, trimmean, triplequad, triu,
vander, vectorfield, ver,
what, who, whos, wilkinson,
zeros, zeta
The following Matlab function names have been capitalized in 'pracma' to avoid shadowing func-
tions from R base or one of its recommended packages (on request of Bill Venables and because of
Brian Ripley's CRAN policies):
Diag, factos, finds, Fix, Imag, Lcm, Mode, Norm, nullspace (<-null),</pre>
Poly,Rank,Real,Reshape,strRep,strTrim,Toeplitz,Trace,uniq (<-unique).
To use "ans" instead of "ans()" - as is common practice in Matlab - type (and similar for other
Matlab commands):
makeActiveBinding("ans",function() .Last.value,.GlobalEnv)
makeActiveBinding("who",who(),.GlobalEnv)
```

```

abm3pc

Adams-Bashford-Moulton

#### **Description**

Third-order Adams-Bashford-Moulton predictor-corrector method.

## Usage

```
abm3pc(f, a, b, y0, n = 50, ...)
```

## **Arguments**

f	function in the differential equation $y' = f(x, y)$ .
a, b	endpoints of the interval.
y0	starting values at point a.
n	the number of steps from a to b.
	additional parameters to be passed to the function.

12 accumarray

## **Details**

Combined Adams-Bashford and Adams-Moulton (or: multi-step) method of third order with corrections according to the predictor-corrector approach.

#### Value

List with components x for grid points between a and b and y a vector y the same length as x; additionally an error estimation est.error that should be looked at with caution.

## Note

This function serves demonstration purposes only.

## References

lines(abm2$x, abm2$y, type = "1", col = "red")
grid()
## End(Not run)</pre>
```

accumarray

Accumulate Vector Elements

## **Description**

accumarray groups elements from a data set and applies a function to each group.

# Usage

```
accumarray(subs, val, sz = NULL, func = sum, fillval = 0)
uniq(a, first = FALSE)
```

accumarray 13

# Arguments

subs	vector or matrix of positive integers, used as indices for the result vector.
val	numerical vector.
SZ	size of the resulting array.
func	function to be applied to a vector of numbers.
fillval	value used to fill the array when there are no indices pointing to that component.
а	numerical vector.
first	logical, shall the first or last element encountered be used.

## **Details**

A <-accumarray(subs,val) creates an array A by accumulating elements of the vector val using the lines of subs as indices and applying func to that accumulated vector. The size of the array can be predetermined by the size vector sz.

A = uniq(a) returns a vector b identical to unique(a) and two other vectors of indices m and n such that b == a[m] and a == b[n].

#### Value

accumarray returns an array of size the maximum in each column of subs, or by sz. uniq returns a list with components

```
b vector of unique elements of a.m vector of indices such that b = a[m]n vector of indices such that a = b[n]
```

#### Note

The Matlab function accumarray can also handle sparse matrices.

#### See Also

unique

```

## Examples for uniq
a <- c(1, 1, 5, 6, 2, 3, 3, 9, 8, 6, 2, 4)
A <- uniq(a); A
# A$b 1 5 6 2 3 9 8 4
# A$m 2 3 10 11 7 8 9 12
# A$n 1 1 2 3 4 5 5 6 7 3 4 8
A <- uniq(a, first = TRUE); A
# A$m 1 3 4 5 6 8 9 12
## Example: Subset sum problem
# Distribution of unique sums among all combinations of a vectors.
allsums <- function(a) {
   S <- c(); C <- c()
   for (k in 1:length(a)) {
       U \leftarrow uniq(c(S, a[k], S + a[k]))
       S <- U$b
       C \leftarrow accumarray(U$n, c(C, 1, C))
   o <- order(S); S <- S[o]; C <- C[o]</pre>
   return(list(S = S, C = C))
}
A \leftarrow allsums(seq(1, 9, by=2)); A
# A$S 1 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 24 25
```

agmean 15

## **Description**

The arithmetic-geometric mean of real or complex numbers.

## Usage

```
agmean(a, b)
```

## **Arguments**

a, b vectors of real or complex numbers of the same length (or scalars).

## **Details**

The arithmetic-geometric mean is defined as the common limit of the two sequences  $a_{n+1} = (a_n + b_n)/2$  and  $b_{n+1} = \sqrt{(a_n b_n)}$ .

When used for negative or complex numbers, the complex square root function is applied.

#### Value

Returns a list with compoinents: agm a vector of arithmetic-geometric means, component-wise, niter the number of iterations, and prec the overall estimated precision.

## Note

Gauss discovered that elliptic integrals can be effectively computed via the arithmetic-geometric mean (see example below), for example:

$$\int_{0}^{\pi/2} \frac{dt}{\sqrt{1 - m^2 sin^2(t)}} = \frac{(a+b)\pi}{4 \cdot agm(a,b)}$$

where m = (a - b)/(a + b)

## References

#### See Also

Arithmetic, geometric, and harmonic mean.

```
## Accuracy test: Gauss constant
1/agmean(1, sqrt(2))$agm - 0.834626841674073186 # 1.11e-16 < eps = 2.22e-16
## Gauss' AGM-based computation of \pi
a <- 1.0
b <- 1.0/sqrt(2)
s <- 0.5
d <- 1L</pre>
```

16 aitken

```
while (abs(a-b) > eps()) {
    t <- a
    a \leftarrow (a + b)*0.5
    b <- sqrt(t*b)
    c <- (a-t)*(a-t)
    d \leftarrow 2L * d
    s <- s - d*c
}
approx_pi <- (a+b)^2 / s / 2.0
                                   # 8.881784e-16 in 4 iterations
abs(approx_pi - pi)
## Example: Approximate elliptic integral
N <- 20
m \leftarrow seq(0, 1, len = N+1)[1:N]
E <- numeric(N)</pre>
for (i in 1:N) {
    f \leftarrow function(t) \frac{1}{sqrt(1 - m[i]^2 * sin(t)^2)}
    E[i] \leftarrow quad(f, 0, pi/2)
A <- numeric(2*N-1)
a <- 1
b <- a * (1-m) / (m+1)
## Not run:
plot(m, E, main = "Elliptic Integrals vs. arith.-geom. Mean")
lines(m, (a+b)*pi / 4 / agmean(a, b)$agm, col="blue")
grid()
## End(Not run)
```

aitken

Aitken' Method

## **Description**

Aitken's acceleration method.

## Usage

```
aitken(f, x0, nmax = 12, tol = 1e-8, ...)
```

## **Arguments**

f	Function with a fixpoint.
x0	Starting value.

nmax Maximum number of iterations.

tol Relative tolerance.

. . . Additional variables passed to f.

akimaInterp 17

## **Details**

Aitken's acceleration method, or delta-squared process, is used for accelerating the rate of convergence of a sequence (from linear to quadratic), here applied to the fixed point iteration scheme of a function.

## Value

The fixpoint (as found so far).

#### Note

Sometimes used to accerate Newton-Raphson (Steffensen's method).

akimaInterp

Univariate Akima Interpolation

## **Description**

Interpolate smooth curve through given points on a plane.

# Usage

```
akimaInterp(x, y, xi)
```

# **Arguments**

```
x, y x/y-coordinates of (irregular) grid points defining the curve.
```

xi x-coordinates of points where to interpolate.

18 akimaInterp

#### **Details**

Implementation of Akima's univariate interpolation method, built from piecewise third order polynomials. There is no need to solve large systems of equations, and the method is therefore computationally very efficient.

## Value

Returns the interpolated values at the points xi as a vector.

#### Note

There is also a 2-dimensional version in package 'akima'.

## Author(s)

Matlab code by H. Shamsundar under BSC License; re-implementation in R by Hans W Borchers.

and, or

and, or

Logical AND, OR (Matlab Style)

# Description

```
and (1,k) resp. or (1,k) the same as (1 \& k) + 0 resp. (1 \mid k) + 0.
```

# Usage

```
and(1, k) or(1, k)
```

# Arguments

1, k Arrays.

# **Details**

Performs a logical operation of arrays 1 and k and returns an array containing elements set to either 1 (TRUE) or 0 (FALSE), that is in Matlab style.

## Value

Logical vector.

20 andrewsplot

andrewsplot Andrews' Curves
-----------------------------

# **Description**

Plots Andrews' curves in cartesian or polar coordinates.

# Usage

```
andrewsplot(A, f, style = "pol", scaled = FALSE, npts = 101)
```

# Arguments

Α	numeric matrix with at least two columns.
f	factor or integer vector with nrow(A) elements.
style	character variable, only possible values 'cart' or 'pol'.
scaled	logical; if true scales each column to have mean 0 and standard deviation 1 (not yet implemented).
npts	number of points to plot.

# **Details**

andrewsplot creates an Andrews plot of the multivariate data in the matrix A, assigning different colors according to the factor or integer vector f.

Andrews' plot represent each observation (row) by a periodic function over the interval [0,2\*pi]. This function for the i-th observation is defined as ...

The plot can be seen in cartesian or polar coordinates — the latter seems appropriate as all these functions are periodic.

#### Value

Generates a plot, no return value.

#### Note

Please note that a different ordering of the columns will result in quite different functions and overall picture.

There are variants utilizing principal component scores, in order of decreasing eigenvalues.

angle

Basic Complex Functions

# **Description**

Basic complex functions (Matlab style)

## Usage

```
Real(z)
Imag(z)
angle(z)
```

# **Arguments**

z

Vector or matrix of real or complex numbers

# **Details**

These are just Matlab names for the corresponding functions in R. The angle function is simply defined as atan2(Im(z),Re(z)).

#### Value

returning real or complex values; angle returns in radians.

#### Note

The true Matlab names are real, imag, and conj, but as real was taken in R, all these beginnings are changed to capitals.

The function Mod has no special name in Matlab; use abs() instead.

# See Also

Mod, abs

22 anms

## **Examples**

```
z <- c(0, 1, 1+1i, 1i)
Real(z)  # Re(z)
Imag(z)  # Im(z)
Conj(z)  # Conj(z)
abs(z)  # Mod(z)
angle(z)</pre>
```

anms

Adaptive Nelder-Mead Minimization

# Description

An implementation of the Nelder-Mead algorithm for derivative-free optimization / function minimization.

# Usage

```
anms(fn, x0, ...,
tol = 1e-10, maxfeval = NULL)
```

# **Arguments**

fn nonlinear function to be minimized.

x0 starting vector.

tol relative tolerance, to be used as stopping rule.

maxfeval maximum number of function calls.

... additional arguments to be passed to the function.

#### **Details**

Also called a 'simplex' method for finding the local minimum of a function of several variables. The method is a pattern search that compares function values at the vertices of the simplex. The process generates a sequence of simplices with ever reducing sizes.

anms can be used up to 20 or 30 dimensions (then 'tol' and 'maxfeval' need to be increased). It applies adaptive parameters for simplicial search, depending on the problem dimension – see Fuchang and Lixing (2012).

With upper and/or lower bounds, anms will apply a transformation of bounded to unbounded regions before utilizing Nelder-Mead. Of course, if the optimum is near to the boundary, results will not be as accurate as when the minimum is in the interior.

## Value

List with following components:

xmin minimum solution found. fmin value of f at minimum.

nfeval number of function calls performed.

approx\_entropy 23

# Note

approx\_entropy

Approximate and Sample Entropy

## Description

Calculates the approximate or sample entropy of a time series.

24 approx\_entropy

## Usage

```
approx_entropy(ts, edim = 2, r = 0.2*sd(ts), elag = 1)
sample_entropy(ts, edim = 2, r = 0.2*sd(ts), tau = 1)
```

#### Arguments

ts	a time series.
edim	the embedding dimension, as for chaotic time series; a preferred value is 2.
r	filter factor; work on heart rate variability has suggested setting r to be $0.2$ times the standard deviation of the data.
elag	embedding lag; defaults to 1, more appropriately it should be set to the smallest lag at which the autocorrelation function of the time series is close to zero. (At the moment it cannot be changed by the user.)
tau	delay time for subsampling, similar to elag.

#### **Details**

Approximate entropy was introduced to quantify the the amount of regularity and the unpredictability of fluctuations in a time series. A low value of the entropy indicates that the time series is deterministic; a high value indicates randomness.

Sample entropy is conceptually similar with the following differences: It does not count self-matching, and it does not depend that much on the length of the time series.

#### Value

The approximate, or sample, entropy, a scalar value.

# Note

This code here derives from Matlab versions at Mathwork's File Exchange, "Fast Approximate Entropy" and "Sample Entropy" by Kijoon Lee under BSD license.

arclength

Arc Length of a Curve

## **Description**

Calculates the arc length of a parametrized curve.

## Usage

```
arclength(f, a, b, nmax = 20, tol = 1e-05, ...)
```

26 arclength

## Arguments

f	parametrization of a curve in n-dim. space.
a,b	begin and end of the parameter interval.
nmax	maximal number of iterations.
tol	relative tolerance requested.
	additional arguments to be passed to the function.

## **Details**

Calculates the arc length of a parametrized curve in R^n. It applies Richardson's extrapolation by refining polygon approximations to the curve.

```
The parametrization of the curve must be vectorized: if t-->F(t) is the parametrization, F(c(t1,t1,...)) must return c(F(t1),F(t2),...).
```

Can be directly applied to determine the arc length of a one-dimensional function f:R-->R by defining F (if f is vectorized) as F:t-->c(t,f(t)).

#### Value

Returns a list with components length the calculated arc length, niter the number of iterations, and rel.err the relative error generated from the extrapolation.

#### Note

If by chance certain equidistant points of the curve lie on a straight line, the result may be wrong, then use polylength below.

## End(Not run)
```

arnoldi

Arnoldi Iteration

## **Description**

Arnoldi iteration generates an orthonormal basis of the Krylov space and a Hessenberg matrix.

# Usage

```
arnoldi(A, q, m)
```

# **Arguments**

A a square n-by-n matrix.

q a vector of length n.

m an integer.

# **Details**

arnoldi (A,q,m) carries out m iterations of the Arnoldi iteration with n-by-n matrix A and starting vector q (which need not have unit 2-norm). For m < n it produces an n-by-(m+1) matrix Q with orthonormal columns and an (m+1)-by-m upper Hessenberg matrix H such that  $A*Q[,1:m] = Q[,1:m]*H[1:m,1:m] + H[m+1,m]*Q[,m+1]*t(E_m)$ , where  $E_m$  is the m-th column of the m-by-m identity matrix.

#### Value

Returns a list with two elements:

Q A matrix of orthonormal columns that generate the Krylov space A, A q, A^2 q, ....

HA Hessenberg matrix such that A = Q \* H \* t(Q).

barylag

Barycentric Lagrange Interpolation

# Description

Barycentric Lagrange interpolation in one dimension.

# Usage

```
barylag(xi, yi, x)
```

## **Arguments**

```
xi, yix- and y-coordinates of supporting nodes.xx-coordinates of interpolation points.
```

# **Details**

barylag interpolates the given data using the barycentric Lagrange interpolation formula (vectorized to remove all loops).

# Value

Values of interpolated data at points x.

30 barylag2d

## Note

Barycentric interpolation is preferred because of its numerical stability.

## End(Not run)
```

barylag2d 31

## **Description**

Two-dimensional barycentric Lagrange interpolation.

#### Usage

```
barylag2d(F, xn, yn, xf, yf)
```

## **Arguments**

F matrix representing values of a function in two dimensions.

xn, yn x- and y-coordinates of supporting nodes.

xf, yf x- and y-coordinates of an interpolating grid..

## **Details**

Well-known Lagrange interpolation using barycentric coordinates, here extended to two dimensions. The function is completely vectorized.

x-coordinates run downwards in F, y-coordinates to the right. That conforms to the usage in image or contour plots, see the example below.

#### Value

Matrix of size length(xf)-by-length(yf) giving the interpolated values at all the grid points (xf,yf).

#### Note

bernoulli

Bernoulli Numbers and Polynomials

## **Description**

The Bernoulli numbers are a sequence of rational numbers that play an important role for the series expansion of hyperbolic functions, in the Euler-MacLaurin formula, or for certain values of Riemann's function at negative integers.

## Usage

```
bernoulli(n, x)
```

#### Arguments

n the index, a whole number greater or equal to 0.

x real number or vector of real numbers; if missing, the Bernoulli numbers will be given, otherwise the polynomial.

bernoulli 33

## **Details**

The calculation of the Bernoulli numbers uses the values of the zeta function at negative integers, i.e.  $B_n = -n zeta(1-n)$ . Bernoulli numbers  $B_n$  for odd n are 0 except  $B_1$  which is set to -0.5 on purpose.

The Bernoulli polynomials can be directly defined as

$$B_n(x) = \sum_{k=0}^n \binom{n}{k} b_{n-k} x^k$$

and it is immediately clear that the Bernoulli numbers are then given as  $B_n = B_n(0)$ .

#### Value

Returns the first n+1 Bernoulli numbers, if x is missing, or the value of the Bernoulli polynomial at point(s) x.

#### Note

The definition uses  $B_1 = -1/2$  in accordance with the definition of the Bernoulli polynomials.

## References

See the entry on Bernoulli numbers in the Wikipedia.

```
## End(Not run)
```

bernstein

Bernstein Polynomials

## **Description**

Bernstein base polynomials and approximations.

## Usage

```
bernstein(f, n, x) bernsteinb(k, n, x)
```

## **Arguments**

f function to be approximated by Bernstein polynomials.

k integer between 0 and n, the k-th Bernstein polynomial of order n.

n order of the Bernstein polynomial(s).

x numeric scalar or vector where the Bernstein polynomials will be calculated.

## **Details**

The Bernstein basis polynomials  $B_{k,n}(x)$  are defined as

$$B_{k,n}(x) = \binom{n}{k} x^k (1-x)^{n-k}$$

and form a basis for the vector space of polynomials of degree n over the interval [0, 1].

bernstein(f,n,x) computes the approximation of function f through Bernstein polynomials of degree n, resp. computes the value of this approximation at x. The function is vectorized and applies a brute force calculation.

But if x is a scalar, the value will be calculated using De Casteljau's algorithm for higher accuracy. For bigger n the binomial coefficients may be in for problems.

## Value

Returns a scalar or vector of function values.

bisect

Rootfinding Through Bisection or Secant Rule

# **Description**

Finding roots of univariate functions in bounded intervals.

## Usage

```
bisect(fun, a, b, maxiter = 500, tol = NA, ...)
secant(fun, a, b, maxiter = 500, tol = 1e-08, ...)
regulaFalsi(fun, a, b, maxiter = 500, tol = 1e-08, ...)
```

# **Arguments**

```
fun Function or its name as a string.

a, b interval end points.

maxiter maximum number of iterations; default 100.
```

36 bisect

```
absolute tolerance; default eps^(1/2)additional arguments passed to the function.
```

## **Details**

"Bisection" is a well known root finding algorithms for real, univariate, continuous functions. Bisection works in any case if the function has opposite signs at the endpoints of the interval.

bisect stops when floating point precision is reached, attaching a tolerance is no longer needed. This version is trimmed for exactness, not speed. Special care is taken when 0.0 is a root of the function. Argument 'tol' is deprecated and not used anymore.

The "Secant rule" uses a succession of roots of secant lines to better approximate a root of a function. "Regula falsi" combines bisection and secant methods. The so-called 'Illinois' improvement is used here.

## Value

Return a list with components root, f.root, the function value at the found root, iter, the number of iterations done, and root, and the estimated accuracy estim.prec

```

bits 37

bits

Binary Representation

# Description

Literal bit representation.

## Usage

```
bits(x, k = 54, pos\_sign = FALSE, break0 = FALSE)
```

## **Arguments**

x a positive or negative floating point number.
 k number of binary digits after the decimal point
 pos\_sign logical; shall the '+' sign be included.
 break0 logical; shall trailing zeros be included.

## **Details**

The literal bit/binary representation of a floating point number is computed by subtracting powers of 2.

## Value

Returns a string containing the binary representation.

## See Also

```
nextpow2
```

38 blkdiag

blanks

String of Blank Carakters

# Description

Create a string of blank characters.

# Usage

```
blanks(n)
```

# Arguments

n

integer greater or equal to 0.

# **Details**

blanks(n) is a string of n blanks.

## Value

String of n blanks.

## See Also

deblank

# **Examples**

blanks(6)

blkdiag

Block Diagonal Matrix

# Description

Build a block diagonal matrix.

# Usage

```
blkdiag(...)
```

# Arguments

sequence of non-empty, numeric matrices

brentDekker 39

## **Details**

Generate a block diagonal matrix from A, B, C, .... All the arguments must be numeric and non-empty matrices.

## Value

a numeric matrix

## Note

Vectors as input have to be converted to matrices before. Note that as.matrix(v) with v a vector will generate a column vector; use matrix(v,nrow=1) if a row vector is intended.

## See Also

Diag

# **Examples**

```
a1 <- matrix(c(1,2), 1)
a2 <- as.matrix(c(1,2))
blkdiag(a1, diag(1, 2, 2), a2)
```

brentDekker

Brent-Dekker Root Finding Algorithm

## **Description**

Find root of continuous function of one variable.

## Usage

```
brentDekker(fun, a, b, maxiter = 500, tol = 1e-12, ...) brent(fun, a, b, maxiter = 500, tol = 1e-12, ...)
```

# Arguments

fun	function whose root is to be found.
a, b	left and right end points of an interval; function values need to be of different sign at the endpoints.
maxiter	maximum number of iterations.
tol	relative tolerance.
	additional arguments to be passed to the function.

40 brown72

## **Details**

brentDekker implements a version of the Brent-Dekker algorithm, a well known root finding algorithms for real, univariate, continuous functions. The Brent-Dekker approach is a clever combination of secant and bisection with quadratic interpolation.

brent is simply an alias for brentDekker.

## Value

brent returns a list with

root location of the root.

f.root funtion value at the root.

f.calls number of function calls.

estim.prec estimated relative precision.

ridders, newtonRaphson

## **Examples**

```
# Legendre polynomial of degree 5
lp5 <- c(63, 0, -70, 0, 15, 0)/8
f <- function(x) polyval(lp5, x)
brent(f, 0.6, 1)  # 0.9061798459 correct to 12 places</pre>
```

brown72

Brownian Motion

## **Description**

The Brown72 data set represents a fractal Brownian motion with a prescribed Hurst exponent 0.72.

## Usage

```
data(brown72)
```

## Format

The format is: one column.

broyden 41

## **Details**

Estimating the Hurst exponent for a data set provides a measure of whether the data is a pure random walk or has underlying trends. Brownian walks can be generated from a defined Hurst exponent.

## **Examples**

```
## Not run:
data(brown72)
plot(brown72, type = "1", col = "blue")
grid()
## End(Not run)
```

broyden

Broyden's Method

## **Description**

Broyden's method for the numerical solution of nonlinear systems of n equations in n variables.

## Usage

# Arguments

Ffun	n functions of n variables.
x0	Numeric vector of length n.
J0	Jacobian of the function at x0.
	additional parameters passed to the function.
maxiter	Maximum number of iterations.
tol	Tolerance, relative accuracy.

## **Details**

F as a function must return a vector of length n, and accept an n-dim. vector or column vector as input. F must not be univariate, that is n must be greater than 1.

Broyden's method computes the Jacobian and its inverse only at the first iteration, and does a rankone update thereafter, applying the so-called Sherman-Morrison formula that computes the inverse of the sum of an invertible matrix A and the dyadic product, uv', of a column vector u and a row vector v'.

#### Value

List with components: zero the best root found so far, fnorm the square root of sum of squares of the values of f, and niter the number of iterations needed.

42 broyden

## Note

Applied to a system of n linear equations it will stop in 2n steps

```

bsxfun 43

bsxfun

Elementwise Function Application (Matlab Style)

## **Description**

Apply a binary function elementwise.

## Usage

```
bsxfun(func, x, y)
arrayfun(func, ...)
```

## **Arguments**

func function with two or more input parameters.

x, y two vectors, matrices, or arrays of the same size.

list of arrays of the same size.

## **Details**

bsxfun applies element-by-element a binary function to two vectors, matrices, or arrays of the same size. For matrices, sweep is used for reasons of speed, otherwise mapply. (For arrays of more than two dimensions this may become very slow.)

arrayfun applies func to each element of the arrays and returns an array of the same size.

## Value

The result will be a vector or matrix of the same size as x, y.

#### Note

The underlying function mapply can be applied in a more general setting with many function parameters:

```
mapply(f,x,y,z,...)
```

but the array structure will not be preserved in this case.

## See Also

Vectorize

44 bulirsch-stoer

## **Examples**

```
X <- matrix(rep(1:10, each = 10), 10, 10)
Y <- t(X)
bsxfun("*", X, Y)  # multiplication table

f <- function(x, y) x[1] * y[1]  # function not vectorized
A <- matrix(c(2, 3, 5, 7), 2, 2)
B <- matrix(c(11, 13, 17, 19), 2, 2)
arrayfun(f, A, B)</pre>
```

bulirsch-stoer

Bulirsch-Stoer Algorithm

#### **Description**

Bulirsch-Stoer algorithm for solving Ordinary Differential Equations (ODEs) very accurately.

## Usage

```
bulirsch_stoer(f, t, y0, ..., tol = 1e-07)
midpoint(f, t0, tfinal, y0, tol = 1e-07, kmax = 25)
```

# Arguments

f	function describing the differential equation $y' = f(t, y)$ .
t	vector of $x$ -values where the values of the ODE function will be computed; needs to be increasingly sorted.
y0	starting values as column vector.
	additional parameters to be passed to the function.
tol	relative tolerance in the Ricardson extrapolation.
t0, tfinal	start and end point of the interval.
kmax	maximal number of steps in the Richardson extrapolation.

## **Details**

The Bulirsch-Stoer algorithm is a well-known method to obtain high-accuracy solutions to ordinary differential equations with reasonable computational efforts. It exploits the midpoint method to get good accuracy in each step.

The (modified) midpoint method computes the values of the dependent variable y(t) from t0 to tfinal by a sequence of substeps, applying Richardson extrapolation in each step.

Bulirsch-Stoer and midpoint shall not be used with non-smooth functions or singularities inside the interval. The best way to get intermediate points t = (t[1], ..., t[n]) may be to call ode23 or ode23s first and use the x-values returned to start bulirsch\_stoer on.

bulirsch-stoer 45

# Value

bulirsch\_stoer returns a list with x the grid points input, and y a vector of function values at the se points.

#### Note

Will be extended to become a full-blown Bulirsch-Stoer implementation.

46 bvp

bν	c

Boundary Value Problems

# Description

Solves boundary value problems of linear second order differential equations.

# Usage

$$bvp(f, g, h, x, y, n = 50)$$

## Arguments

f,g,h	functions on the right side of the differential equation. If f,g or h is a scalar instead of a function, it is assumed to be a constant coefficient in the differential equation.
X	x[1],x[2] are the interval borders where the solution shall be computed.
у	boundary conditions such that $y(x[1]) = y[1], y(x[2]) = y[2]$ .
n	number of intermediate grid points; default 50.

## **Details**

Solves the two-point boundary value problem given as a linear differential equation of second order in the form:

$$y'' = f(x)y' + g(x)y + h(x)$$

with the finite element method. The solution y(x) shall exist on the interval [a,b] with boundary conditions  $y(a) = y_a$  and  $y(b) = y_b$ .

## Value

Returns a list list(xs,ys) with the grid points xs and the values ys of the solution at these points, including the boundary points.

#### Note

Uses a tridiagonal equation solver that may be faster then qr. solve for large values of n.

cart2sph

Coordinate Transformations

## **Description**

Transforms between cartesian, spherical, polar, and cylindrical coordinate systems in two and three dimensions.

#### Usage

```
cart2sph(xyz)
sph2cart(tpr)
cart2pol(xyz)
pol2cart(prz)
```

## **Arguments**

xyz cartesian coordinates x, y, z as vector or matrix.

tpr spherical coordinates theta, phi, and r as vector or matrix.

prz polar coordinates phi, r or cylindrical coordinates phi, r, z as vector or matrix.

#### **Details**

cart2sph returns spherical coordinates as (theta, phi, r), and sph2cart expects them in this sequence.

cart2pol returns polar coordinates (phi, r) if length(xyz)==2 and cylindrical coordinates (phi, r, z) else. pol2cart needs them in this sequence and length.

48 cd, pwd, what

To go from cylindrical to cartesian coordinates, transform to cartesian coordinates first — or write your own function, see the examples.

All transformation functions are vectorized.

#### Value

All functions return a (2- or 3-dimensional) vector representing a point in the requested coordinate system, or a matrix with 2 or 3 named columns where is row represents a point. The columns are named accordingly.

#### Note

In Matlab these functions accept two or three variables and return two or three values. In R it did not appear appropriate to return coordinates as a list.

These functions should be vectorized in the sense that they accept will accept matrices with number of rows or columns equal to 2 or 3.

## **Examples**

```
x <- 0.5*cos(pi/6); y <- 0.5*sin(pi/6); z <- sqrt(1 - x^2 - y^2)

```

cd, pwd, what

Directory Functions (Matlab style)

## **Description**

Displays or changes working directory, or lists files therein.

## Usage

```
cd(dname)
pwd()
what(dname = getwd())
```

## **Arguments**

dname

(relative or absolute) directory path.

ceil 49

## **Details**

pwd() displays the name of the current directory, and is the same as cd(). cd(dname) changes to directory dname and if successfull displays the directory name.

what() lists all files in a directory.

#### Value

Name of the current working directory.

#### See Also

```
getwd, setwd, list.files
```

## **Examples**

```
# cd()
# pwd()
# what()
```

ceil

Integer Functions (Matlab Style)

## **Description**

Functions for rounding and truncating numeric values towards near integer values.

# Usage

```
ceil(n)
Fix(n)
```

## **Arguments**

n

a numeric vector or matrix

#### **Details**

ceil() is an alias for ceiling() and rounds to the smallest integer equal to or above n.

Fix() truncates values towards 0 and is an alias for trunc(). Uses ml prefix to indicate Matlab style.

The corresponding functions floor() (rounding to the largest interger equal to or smaller than n) and round() (rounding to the specified number of digits after the decimal point, default being 0) are already part of R base.

## Value

integer values

50 charpoly

## **Examples**

```
x <- c(-1.2, -0.8, 0, 0.5, 1.1, 2.9)

ceil(x)

Fix(x)
```

charpoly

Characteristic Polynomial

## **Description**

Computes the characteristic polynomial (and the inverse of the matrix, if requested) using the Faddeew-Leverrier method.

## Usage

```
charpoly(a, info = FALSE)
```

# **Arguments**

a quadratic matrix; size should not be much larger than 100. info logical; if true, the inverse matrix will also be reported.

#### **Details**

Computes the characteristic polynomial recursively. In the last step the determinant and the inverse matrix can be determined without any extra cost (if the matrix is not singular).

## Value

Either the characteristic polynomial as numeric vector, or a list with components cp, the characteristic polynomial, det, the determinant, and inv, the inverse matrix, will be returned.

## References

Hou, S.-H. (1998). Classroom Note: A Simple Proof of the Leverrier–Faddeev Characteristic Polynomial Algorithm, SIAM Review, 40(3), pp. 706–709.

a <- magic(5)
A <- charpoly(a, info = TRUE)
A$cp
roots(A$cp)
A$det
zapsmall(A$inv %*% a)</pre>
```

chebApprox 51

chebApprox	Chebyshev Approximation	

# Description

Function approximation through Chebyshev polynomials (of the first kind).

## Usage

```
chebApprox(x, fun, a, b, n)
```

## **Arguments**

Χ	Numeric vector of points within interval [a,b].
---	---

fun Function to be approximated.

a, b Endpoints of the interval.

n An integer  $\geq = 0$ .

#### **Details**

Return approximate y-coordinates of points at x by computing the Chebyshev approximation of degree n for fun on the interval [a,b].

# Value

A numeric vector of the same length as x.

## Note

TODO: Evaluate the Chebyshev approximative polynomial by using the Clenshaw recurrence formula. (Not yet vectorized, that's why we still use the Horner scheme.)

# References

Press, W. H., S. A. Teukolsky, W. T. Vetterling, and B. P. Flannery (1992). Numerical Recipes in C: The Art of Scientific Computing. Second Edition, Cambridge University Press.

lines(x, yp, col = "navy")
lines(x, yc, col = "red")
grid()
## End(Not run)
```

chebCoeff

Chebyshev Polynomials

# Description

Chebyshev Coefficients for Chebyshev polynomials of the first kind.

# Usage

```
chebCoeff(fun, a, b, n)
```

## **Arguments**

```
fun function to be approximated.

a, b endpoints of the interval.

n an integer >= 0.
```

# **Details**

For a function fun on on the interval [a,b] determines the coefficients of the Chebyshev polynomials up to degree n that will approximate the function (in L2 norm).

chebPoly 53

## Value

Vector of coefficients for the Chebyshev polynomials, from low to high degrees (see the example).

#### Note

See the "Chebfun Project" <a href="https://www.chebfun.org/">https://www.chebfun.org/</a> by Nick Trefethen.

#### References

p < -cC \%*\% cP # 0 0 1 0 1
```

chebPoly

Chebyshev Polynomials

## **Description**

Chebyshev polynomials and their values.

## Usage

```
chebPoly(n, x = NULL)
```

## **Arguments**

```
n an integer \geq = 0.
```

x a numeric vector, possibly empty; default NULL.

## **Details**

Determines an (n+1)-ny-(n+1)-Matrix of Chebyshev polynomials up to degree n.

The coefficients of the first n Chebyshev polynomials are computed using the recursion formula. For computing any values at points the well known Horner schema is applied.

54 circlefit

## Value

If x is NULL, returns an (n+1)-by-(n+1) matrix with the coefficients of the first Chebyshev polynomials from 0 to n, one polynomial per row with coefficients from highest to lowest order.

If x is a numeric vector, returns the values of the n-th Chebyshev polynomial at the points of x.

## Note

## **Examples**

circlefit

Fitting a Circle

# Description

Fitting a circle from points in the plane

## Usage

```
circlefit(xp, yp, fast = TRUE)
```

circlefit 55

## Arguments

xp, yp	Vectors representing the x and y coordinates of plane points
fast	deprecated; will not be used.

## **Details**

This routine finds an 'algebraic' solution based on a linear fit. The value to be minimized is the distance of the given points to the nearest point on the circle along a radius.

#### Value

Returns x- and y-coordinates of the center and the radius as a vector of length 3.

Writes the RMS error of the (radial) distance of the original points to the circle directly onto the console.

#### References

lines(xx, yy, col="blue")
## End(Not run)
```

clear, who(s), ver

```
clear, who(s), ver Clear function (Matlab style)
```

# Description

List or remove items from workspace, or display system information.

# Usage

```
clear(lst)
ver()
who()
whos()
```

# Arguments

lst

Character vector of names of variables in the global environment.

## **Details**

Remove these or all items from the workspace, i.e. the global environment, and freeing up system memory.

```
who() lists all items on the workspace.
```

whos() lists all items and their class and size.

ver() displays version and license information for R and all the loaded packages.

# Value

Invisibly NULL.

clenshaw\_curtis 57

clenshaw\_curtis

Clenshaw-Curtis Quadrature Formula

## **Description**

Clenshaw-Curtis Quadrature Formula

## Usage

```
clenshaw_curtis(f, a = -1, b = 1, n = 1024, ...)
```

## **Arguments**

f	function, the integrand, without singularities.
a, b	lower and upper limit of the integral; must be finite.
n	Number of Chebyshev nodes to account for.
	Additional parameters to be passed to the function

## **Details**

Clenshaw-Curtis quadrature is based on sampling the integrand on Chebyshev points, an operation that can be implemented using the Fast Fourier Transform.

## Value

Numerical scalar, the value of the integral.

58 compan

combs

Generate Combinations

# Description

Generates all combinations of length m of a vector a.

## Usage

```
combs(a, m)
```

# Arguments

a numeric vector of some length n

m integer with  $0 \le m \le n$ 

## **Details**

combs generates combinations of length n of the elements of the vector a.

# Value

matrix representing combinations of the elements of a

## See Also

```
perms, randcomb
```

# **Examples**

```
combs(seq(2, 10, by=2), m = 3)
```

compan

Companion Matrix

# Description

Computes the companion matrix of a real or complex vector.

# Usage

```
compan(p)
```

# Arguments

р

vector representing a polynomial

complexstep 59

## **Details**

Computes the companion matrix corresponding to the vector p with -p[2:length(p)]/p[1] as first row.

The eigenvalues of this matrix are the roots of the polynomial.

## Value

A square matrix of length(p)-1 rows and columns

#### See Also

roots

## **Examples**

```
p <- c(1, 0, -7, 6)
compan(p)
# 0 7 -6
# 1 0 0
# 0 1 0
```

complexstep

Complex Step Derivatives

# Description

Complex step derivatives of real-valued functions, including gradients, Jacobians, and Hessians.

# Usage

```
complexstep(f, x0, h = 1e-20, ...)
grad_csd(f, x0, h = 1e-20, ...)
jacobian_csd(f, x0, h = 1e-20, ...)
hessian_csd(f, x0, h = 1e-20, ...)
laplacian_csd(f, x0, h = 1e-20, ...)
```

## **Arguments**

f	Function that is to be differentiated.
x0	Point at which to differentiate the function.
h	Step size to be applied; shall be very small.
	Additional variables to be passed to f.

60 complexstep

#### **Details**

Complex step derivation is a fast and highly exact way of numerically differentiating a function. If the following conditions are satisfied, there will be no loss of accuracy between computing a function value and computing the derivative at a certain point.

- f must have an analytical (i.e., complex differentiable) continuation into an open neighborhood of x0.
- x0 and f(x0) must be real.
- h is real and *very* small: 0 < h << 1.

complexstep handles differentiation of univariate functions, while grad\_csd and jacobian\_csd compute gradients and Jacobians by applying the complex step approach iteratively. Please understand that these functions are not vectorized, but complexstep is.

As complex step cannot be applied twice (the first derivative does not fullfil the conditions), hessian\_csd works differently. For the first derivation, complex step is used, to the one time derived function Richardson's method is applied. The same applies to lapalacian\_csd.

#### Value

```
complexstep(f,x0) returns the derivative f'(x_0) of f at x_0. The function is vectorized in x0.
```

#### Note

This surprising approach can be easily deduced from the complex-analytic Taylor formula.

cond

Matrix Condition

## **Description**

Condition number of a matrix.

## Usage

```
cond(M, p = 2)
```

# Arguments

M Numeric matrix; vectors will be considered as column vectors.

p Indicates the p-norm. At the moment, norms other than p=2 are not implemented.

## **Details**

The condition number of a matrix measures the sensitivity of the solution of a system of linear equations to small errors in the data. Values of cond(M) and cond(M,p) near 1 are indications of a well-conditioned matrix.

62 conv

## Value

cond(M) returns the 2-norm condition number, the ratio of the largest singular value of M to the smallest.

```
c = cond(M,p) returns the matrix condition number in p-norm:
```

```
norm(X,p) * norm(inv(X),p).
(Not yet implemented.)
```

## Note

Not feasible for large or sparse matrices as svd(M) needs to be computed. The Matlab/Octave function condest for condition estimation has not been implemented.

conv

Polynomial Convolution

## **Description**

Convolution and polynomial multiplication.

## Usage

```
conv(x, y)
```

## **Arguments**

х, у

real or complex vectors.

#### **Details**

r = conv(p,q) convolves vectors p and q. Algebraically, convolution is the same operation as multiplying the polynomials whose coefficients are the elements of p and q.

## Value

Another vector.

cot,csc,sec, etc. 63

## Note

conv utilizes fast Fourier transformation.

#### See Also

```
deconv, polyadd
```

## **Examples**

```
conv(c(1, 1, 1), 1)
conv(c(1, 1, 1), c(0, 0, 1))
conv(c(-0.5, 1, -1), c(0.5, 0, 1))
```

cot,csc,sec, etc.

More Trigonometric Functions

# **Description**

More trigonometric functions not available in R.

## Usage

cot(z)
csc(z)
sec(z)
acot(z)
acsc(z)

asec(z)

## **Arguments**

z numeric or complex scalar or vector.

## **Details**

The usual trigonometric cotangens, cosecans, and secans functions and their inverses, computed through the other well known – in R – sine, cosine, and tangens functions.

## Value

Result vector of numeric or complex values.

## Note

These function names are available in Matlab, that is the reason they have been added to the 'pracma' package.

64 cotes

## See Also

Trigonometric and hyperbolic functions in R.

## **Examples**

```

asec(1+1i) # 1.1185 + 0.5306i
```

cotes

Newton-Cotes Formulas

# Description

Closed composite Newton-Cotes formulas of degree 2 to 8.

## Usage

```
cotes(f, a, b, n, nodes, ...)
```

## **Arguments**

f	the integrand as function of two variables.
a, b	lower and upper limit of the integral.
n	number of subintervals (grid points).
nodes	number of nodes in the Newton-Cotes formula.
	additional parameters to be passed to the function.

## **Details**

2 to 8 point closed and summed Newton-Cotes numerical integration formulas.

These formulas are called 'closed' as they include the endpoints. They are called 'composite' insofar as they are combined with a Lagrange interpolation over subintervals.

## Value

The integral as a scalar.

## Note

It is generally recommended not to apply Newton-Cotes formula of degrees higher than 6, instead increase the number n of subintervals used.

coth,csch,sech, etc. 65

## Author(s)

Standard Newton-Cotes formulas can be found in every textbook. Copyright (c) 2005 Greg von Winckel of nicely vectorized Matlab code, available from MatlabCentral, for 2 to 11 grid points. R version by Hans W Borchers, with permission.

cranknic

Crank-Nicolson Method

## **Description**

The Crank-Nicolson method for solving ordinary differential equations is a combination of the generic steps of the forward and backward Euler methods.

#### Usage

```
cranknic(f, t0, t1, y0, ..., N = 100)
```

# **Arguments**

```
f function in the differential equation y' = f(x,y); defined as a function R \times R^m \to R^m, where m is the number of equations. t0, t1 start and end points of the interval. y0 starting values as row or column vector; for m equations y0 needs to be a vector of length m. N number of steps. Additional parameters to be passed to the function.
```

#### **Details**

Adding together forward and backword Euler method in the cranknic method is by finding the root of the function merging these two formulas.

No attempt is made to catch any errors in the root finding functions.

cranknic 67

#### Value

List with components t for grid (or 'time') points between t0 and t1, and y an n-by-m matrix with solution variables in columns, i.e. each row contains one time stamp.

## Note

This is for demonstration purposes only; for real problems or applications please use ode23 or rkf54.

```

68 cross

cross

Vector Cross Product

# **Description**

Vector or cross product

## Usage

```
cross(x, y)
```

## **Arguments**

x numeric vector or matrix y numeric vector or matrix

## **Details**

Computes the cross (or: vector) product of vectors in 3 dimensions. In case of matrices it takes the first dimension of length 3 and computes the cross product between corresponding columns or rows.

The more general cross product of n-1 vectors in n-dimensional space is realized as crossn.

## Value

3-dim. vector if x and < are vectors, a matrix of 3-dim. vectors if x and y are matrices themselves.

## See Also

```
dot, crossn
```

```
cross(c(1, 2, 3), c(4, 5, 6)) # -3 6 -3
```

crossn 69

crossn

n-dimensional Vector Cross Product

## **Description**

Vector cross product of n-1 vectors in n-dimensional space

## Usage

```
crossn(A)
```

## **Arguments**

Α

matrix of size (n-1) x n where  $n \ge 2$ .

#### **Details**

The rows of the matrix A are taken as(n-1) vectors in n-dimensional space. The cross product generates a vector in this space that is orthogonal to all these rows in A and its length is the volume of the geometric hypercube spanned by the vectors.

## Value

```
a vector of length n
```

## Note

```
The 'scalar triple product' in R^3 can be defined as spatproduct <-function(a,b,c) dot(a,crossn(b,c))
```

It represents the volume of the parallelepiped spanned by the three vectors.

# See Also

```
cross, dot
```

```
A <- matrix(c(1,0,0,0,1,0), nrow=2, ncol=3, byrow=TRUE) crossn(A) #=> 0 0 1 
 x <- c(1.0, 0.0, 0.0) y <- c(1.0, 0.5, 0.0) z <- c(0.0, 0.0, 1.0) identical(dot(x, crossn(rbind(y, z))), det(rbind(x, y, z)))
```

70 cubicspline

			-		
cub	Ť.	CST	١ı	1	ne

Interpolating Cubic Spline

# Description

Computes the natural interpolation cubic spline.

## Usage

```
cubicspline(x, y, xi = NULL, endp2nd = FALSE, der = c(0, 0))
```

## **Arguments**

x, y	x- and y-coordinates of	f points to be interpolated.

xi x-coordinates of points at which the interpolation is to be performed.

endp2nd logical; if true, the derivatives at the endpoints are prescribed by der.

der a two-components vector prescribing derivatives at endpoints.

## **Details**

cubicspline computes the values at xi of the natural interpolating cubic spline that interpolate the values y at the nodes x. The derivatives at the endpoints can be prescribed.

## Value

Returns either the interpolated values at the points xi or, if is.null(xi), the piecewise polynomial that represents the spline.

## Note

From the piecewise polynomial returned one can easily generate the spline function, see the examples.

                                                  # der = 0 at endpoints
lines(xs, ys, col = "red")
ys <- cubicspline(x, y, xs)</pre>
                                                  # no endpoint condition
lines(xs, ys, col = "darkred")
## End(Not run)
```

curvefit

Parametric Curve Fit

## **Description**

Polynomial fitting of parametrized points on 2D curves, also requiring to meet some points exactly.

## Usage

```
curvefit(u, x, y, n, U = NULL, V = NULL)
```

# Arguments

u	the parameter vector.
x, y	x-, y-coordinates for each parameter value.
n	order of the polynomials, the same in x- and y-direction.
U	parameter values where points will be fixed.
V	matrix with two columns and lemgth(U) rows; first column contains the x-, the second the y-values of those points kept fixed.

72 curvefit

## **Details**

This function will attempt to fit two polynomials to parametrized curve points using the linear least squares approach with linear equality constraints in lsqlin. The requirement to meet exactly some fixed points is interpreted as a linear equality constraint.

## Value

Returns a list with 4 components, xp and yp coordinates of the fitted points, and px and py the coefficients of the fitting polynomials in x- and y-direction.

#### Note

In the same manner, derivatives/directions could be prescribed at certain points.

#### See Also

cutpoints

Find Cutting Points

### **Description**

Finds cutting points for vector s of real numbers.

## Usage

```
cutpoints(x, nmax = 8, quant = 0.95)
```

## **Arguments**

x vector of real values.

nmax the maximum number of cutting points to choose

quantile of the gaps to consider for cuts.

#### **Details**

Finds cutting points for vector s of real numbers, based on the gaps in the values of the vector. The number of cutting points is derived from a quantile of gaps in the values. The user can set a lower limit for this number of gaps.

#### Value

Returns a list with components cutp, the cutting points selected, and cutd, the gap between values of x at this cutting point.

## Note

Automatically finding cutting points is often requested in Data Mining. If a target attribute is available, Quinlan's C5.0 does a very good job here. Unfortunately, the 'C5.0' package (of the R-Forge project "Rulebased Models") is quite cumbersome to use.

dblquad

Double and Triple Integration

## **Description**

Numerically evaluate double integral over rectangle.

dblquad 75

### Usage

# Arguments

f	function of two variables, the integrand.
xa, xb	left and right endpoint for first variable.
ya, yb	left and right endpoint for second variable.
za, zb	left and right endpoint for third variable.
dim	which variable to integrate first.
subdivs	number of subdivisions to use.
tol	relative tolerance to use in integrate.
	additional parameters to be passed to the integrand.

### **Details**

Function dblquad applies the internal single variable integration function integrate two times, once for each variable.

Function triplequad reduces the problem to dblquad by first integrating over the innermost variable.

### Value

Numerical scalar, the value of the integral.

#### See Also

integrate, quad2d, simpson2d

```
f1 <- function(x, y) x^2 + y^2

76 deconv

deconv

Deconvolution

# **Description**

Deconvolution and polynomial division.

# Usage

```
deconv(b, a)
```

# Arguments

b, a

real or complex vectors.

### **Details**

deconv(b,a) deconvolves vector a out of vector b. The quotient is returned in vector q and the remainder in vector r such that b = conv(a,q)+r.

If b and a are vectors of polynomial coefficients, convolving them is equivalent to multiplying the two polynomials, and deconvolution is polynomial division.

# Value

List with elements named q and r.

#### Note

TODO: Base deconv on some filter1d function.

### See Also

```
conv, polymul
```

```
b <- c(10, 40, 100, 160, 170, 120)
a <- c(1, 2, 3, 4)

p$q  #=> 10 20 30
p$r  #=> 0 0 0
```

deeve 77

deeve

Event Detection in ODE solution

#### **Description**

Detect events in solutions of a differential equation.

### Usage

```
deeve(x, y, yv = 0, idx = NULL)
```

# Arguments

X	vector of (time) points at which the differential equation has been solved.
у	values of the function(s) that have been computed for the given (time) points.
yv	point or numeric vector at which the solution is wanted.
idx	index of functions whose vales shall be returned.

### **Details**

Determines when (in x coordinates) the idx-th solution function will take on the value yv. The interpolation is linear for the moment. For points outside the x interval NA is returned.

### Value

A (time) point x0 at which the event happens.

# Note

The interpolation is linear only for the moment.

# See Also

deval

```
## Damped pendulum: y'' = -0.3 y' - sin(y)
# y1 = y, y2 = y': y1' = y2, y2' = -0.3*y2 - sin(y1)
f <- function(t, y) {
    dy1 <- y[2]
    dy2 <- -0.3*y[2] - sin(y[1])
    return(c(dy1, dy2))
}
sol <- rk4sys(f, 0, 10, c(pi/2, 0), 100)

# matplot(sol$x, sol$y); grid()</pre>
```

78 detrend

deg2rad

Degrees to Radians

# **Description**

Transforms between angles in degrees and radians.

# Usage

```
deg2rad(deg)
rad2deg(rad)
```

# **Arguments**

```
deg (array of) angles in degrees.
rad (array of) angles in radians.
```

### **Details**

This is a simple calculation back and forth. Note that angles greater than 360 degrees are allowed and will be returned. This may appear incorrect but follows a corresponding discussion on Matlab Central.

### Value

The angle in degrees or radians.

# **Examples**

```
deg2rad(c(0, 10, 20, 30, 40, 50, 60, 70, 80, 90)) rad2deg(seq(-pi/2, pi/2, length = 19))
```

detrend

Remove Linear Trends

# Description

Removes the mean value or (piecewise) linear trend from a vector or from each column of a matrix.

```
detrend(x, tt = 'linear', bp = c())
```

deval 79

# **Arguments**

X	vector or matrix, columns considered as the time series.
tt	trend type, 'constant' or 'linear', default is 'linear'.
bp	break points, indices between 1 and nrow(x).

# **Details**

detrend computes the least-squares fit of a straight line (or composite line for piecewise linear trends) to the data and subtracts the resulting function from the data.

To obtain the equation of the straight-line fit, use polyfit.

### Value

removes the mean or (piecewise) linear trend from x and returns it in y=detrend(x), that is x-y is the linear trend.

#### Note

Detrending is often used for FFT processing.

## See Also

```
polyfit
```

# **Examples**

```

deval

**Evaluate ODE Solution** 

# Description

Evaluate solution of a differential equation solver.

```
deval(x, y, xp, idx = NULL)
```

Diag Diag

# **Arguments**

X	vector of (time) points at which the differential equation has been solved.
у	values of the function(s) that have been computed for the given (time) points.
хр	point or numeric vector at which the solution is wanted; must be sorted.
idx	index of functions whose vales shall be returned.

### **Details**

Determines where the points xp lie within the vector x and interpolates linearly.

#### Value

```
An length(xp)-by-length(idx) matrix of values at points xp.
```

#### Note

The interpolation is linear only for the moment.

# See Also

deeve

# **Examples**

```
## Free fall: v' = -g - cw abs(v)^1.1, cw = 1.6 drag coefficien
f <- function(t, y) -9.81 + 1.6*abs(y)^1.1
sol <- rk4(f, 0, 10, 0, 100)
# speed after 0.5, 1, 1.5, 2 seconds

# plot(sol$x, -sol$y, type="l", col="blue"); grid()</pre>
```

Diag

Matrix Diagonal

# Description

Generate diagonal matrices or return diagonal of a matrix

```
Diag(x, k = 0)
```

disp,beep 81

# **Arguments**

x vector or matrix

k integer indicating a secondary diagonal

### **Details**

If x is a vector, Diag(x,k) generates a matrix with x as the (k-th secondary) diagonal.

If x is a matrix, Diag(x,k) returns the (k-th secondary) diagonal of x.

The k-th secondary diagonal is above the main diagonal for k > 0 and below the main diagonal for k < 0.

#### Value

matrix or vector

#### Note

In Matlab/Octave this function is called diag() and has a different signature than the corresponding function in R.

# See Also

```
diag, Trace
```

# **Examples**

```
Diag(matrix(1:12,3,4), 1)
Diag(matrix(1:12,3,4), -1)

Diag(c(1,5,9), 1)
Diag(c(1,5,9), -1)
```

disp, beep

Utility functions (Matlab style)

# Description

Display text or array, or produce beep sound.

# Usage

```
disp(...)
beep()
```

## **Arguments**

any R object that can be printed.

82 distmat

### **Details**

Display text or array, or produces the computer's default beep sound using 'cat' with closing new-

#### Value

beep() returns NULL invisibly, disp() displays with newline.

# **Examples**

```
disp("Some text, and numbers:", pi, exp(1))
# beep()
```

distmat

Distance Matrix

# Description

Computes the Euclidean distance between rows of two matrices.

### Usage

```
distmat(X, Y)
pdist(X)
pdist2(X, Y)
```

# Arguments

X matrix of some size m x k; vector will be taken as row matrix.
Y matrix of some size n x k; vector will be taken as row matrix.

## **Details**

Computes Euclidean distance between two vectors A and B as:

```
||A-B|| = sqrt (||A||^2 + ||B||^2 - 2*A.B) and vectorizes to rows of two matrices (or vectors). pdist2 is an alias for distmat, while pdist(X) is the same as distmat(X,X).
```

### Value

matrix of size  $m \times n$  if x is of size  $m \times k$  and y is of size  $n \times k$ .

dot 83

# Note

```
If a is m x r and b is n x r then apply(outer(a,t(b),"-"),c(1,4),function(x)sqrt(sum(diag(x*x))))
```

is the m x n matrix of distances between the m rows of a and n rows of b.

This can be modified as necessary, if one wants to apply distances other than the euclidean.

BUT: The code shown here is 10-100 times faster, utilizing the similarity between Euclidean distance and matrix operations.

```

dot

Scalar Product

### **Description**

'dot' or 'scalar' product of vectors or pairwise columns of matrices.

### Usage

```
dot(x, y)
```

# **Arguments**

```
x numeric vector or matrix
y numeric vector or matrix
```

84 eig

# **Details**

Returns the 'dot' or 'scalar' product of vectors or columns of matrices. Two vectors must be of same length, two matrices must be of the same size. If x and y are column or row vectors, their dot product will be computed as if they were simple vectors.

# Value

A scalar or vector of length the number of columns of x and y.

#### See Also

cross

# **Examples**

eig

Eigenvalue Function (Matlab Style)

# **Description**

Eigenvalues of a matrix

# Usage

eig(a)

# **Arguments**

а

real or complex square matrix

### **Details**

Computes the eigenvalues of a square matrix of real or complex numbers, using the R routine eigen without computing the eigenvectors.

#### Value

Vector of eigenvalues

```

eigjacobi

Jacobi Eigenvalue Method

# **Description**

Jacobi's iteration method for eigenvalues and eigenvectors.

# Usage

```
eigjacobi(A, tol = .Machine$double.eps^(2/3))
```

# Arguments

A a real symmetric matrix.

tol requested tolerance.

#### Details

The Jacobi eigenvalue method repeatedly performs (Givens) transformations until the matrix becomes almost diagonal.

### Value

Returns a list with components V, a matrix containing the eigenvectors as columns, and D a vector of the eigenvalues.

# Note

This R implementation works well up to 50x50-matrices.

einsteinF

Einstein Functions

# Description

Einstein functions.

## Usage

```
einsteinF(d, x)
```

# **Arguments**

x numeric or complex vector.

d parameter to select one of the Einstein functions E1, E2, E3, E4.

# **Details**

The Einstein functions are sometimes used for the Planck-Einstein oscillator in one degree of freedom.

The functions are defined as:

$$E1(x) = \frac{x^2 e^x}{(e^x - 1)^2}$$

$$E2(x) = \frac{x}{e^x - 1}$$

$$E3(x) = \ln(1 - e^{-x})$$

$$E4(x) = \frac{x}{e^x - 1} - \ln(1 - e^{-x})$$

E1 has an inflection point as x=2.34694130...

ellipke,ellipj 87

### Value

Numeric/complex scalar or vector.

## **Examples**

```
## Not run:
x1 < - seq(-4, 4, length.out = 101)
y1 \leftarrow einsteinF(1, x1)
plot(x1, y1, type = "1", col = "red",
              xlab = "", ylab = "", main = "Einstein Function E1(x)")
grid()
y2 \leftarrow einsteinF(2, x1)
plot(x1, y2, type = "l", col = "red",
              xlab = "", ylab = "", main = "Einstein Function E2(x)")
grid()
x3 <- seq(0, 5, length.out = 101)
y3 \leftarrow einsteinF(3, x3)

grid()
## End(Not run)
```

ellipke,ellipj

Elliptic and Jacobi Elliptic Integrals

# **Description**

Complete elliptic integrals of the first and second kind, and Jacobi elliptic integrals.

#### **Usage**

```
ellipke(m, tol = .Machine$double.eps)
ellipj(u, m, tol = .Machine$double.eps)
```

#### **Arguments**

```
u numeric vector.

m input vector, all input elements must satisfy 0 <= x <= 1.

tol tolerance; default is machine precision.
```

88 ellipke,ellipj

### **Details**

ellipke computes the complete elliptic integrals to accuracy tol, based on the algebraic-geometric mean.

ellipj computes the Jacobi elliptic integrals sn, cn, and dn. For instance, sn is the inverse function for

$$u = \int_0^\phi dt / \sqrt{1 - m \sin^2 t}$$

with  $sn(u) = \sin(\phi)$ .

Some definitions of the elliptic functions use the modules k instead of the parameter m. They are related by  $k^2=m=\sin(a)^2$  where a is the 'modular angle'.

#### Value

ellipke returns list with two components, k the values for the first kind, e the values for the second kind

ellipj returns a list with components the three Jacobi elliptic integrals sn, cn, and dn.

#### References

Abramowitz, M., and I. A. Stegun (1965). Handbook of Mathematical Functions. Dover Publications, New York.

eps 89

eps

Floating Point Relative Accuracy

### **Description**

Distance from 1.0 to the next largest double-precision number.

# Usage

```
eps(x = 1.0)
```

## **Arguments**

Х

scalar or numerical vector or matrix.

#### **Details**

d=eps(x) is the positive distance from abs(x) to the next larger floating point number in double precision.

If x is an array, eps(x) will return eps(max(abs(x))).

# Value

Returns a scalar.

```
for (i in -5:5) cat(eps(10^i), "\n")
# 1.694066e-21
# 1.355253e-20
# 2.168404e-19

# 1.455192e-11
```

90 erf

erf

Error Functions and Inverses (Matlab Style)

# Description

The error or Phi function is a variant of the cumulative normal (or Gaussian) distribution.

## Usage

```
erf(x)
erfinv(y)
erfc(x)
erfcinv(y)
erfcx(x)
erfz(z)
erfi(z)
```

# Arguments

x, y vector of real numbers.

z real or complex number; must be a scalar.

### **Details**

```
erf and erfinv are the error and inverse error functions.
erfc and erfcinv are the complementary error function and its inverse.
erfcx is the scaled complementary error function.
erfz is the complex, erfi the imaginary error function.
```

### Value

Real or complex number(s), the value(s) of the function.

# Note

For the complex error function we used Fortran code from the book S. Zhang & J. Jin "Computation of Special Functions" (Wiley, 1996).

### Author(s)

First version by Hans W Borchers; vectorized version of erfz by Michael Lachmann.

### See Also

```

errorbar

Plot Error Bars

### **Description**

Draws symmetric error bars in x- and/or y-direction.

# Usage

# Arguments

x, y	x-, y-coordinates
xerr, yerr	length of the error bars, relative to the x-, y-values.
bar.col	color of the error bars; default: red
bar.len	length of the cross bars orthogonal to the error bars; default: 0.01.
grid	logical; should the grid be plotted?; default: true
with	logical; whether to end the error bars with small cross bars.
add	logical; should the error bars be added to an existing plot?; default: false.
	additional plotting parameters that will be passed to the plot function.

### **Details**

errorbar plots y versus x with symmetric error bars, with a length determined by xerr resp. yerr in x- and/or y-direction. If xerr or yerr is NULL error bars in this direction will not be drawn.

A future version will allow to draw unsymmetric error bars by specifying upper and lower limits when xerr or yerr is a matrix of size  $(2 \times length(x))$ .

92 eta

# Value

Generates a plot, no return value.

#### See Also

y <- apply(cnt, 1, mean)
e <- apply(cnt, 1, sd)
errorbar(1:20, y, yerr = e, bar.col = "blue")
## End(Not run)</pre>
```

eta

Dirichlet Eta Function

# **Description**

Dirichlet's eta function valid in the entire complex plane.

# Usage

eta(z)

# **Arguments**

z

Real or complex number or a numeric or complex vector.

## **Details**

Computes the eta function for complex arguments using a series expansion.

Accuracy is about 13 significant digits for abs(z)<100, drops off with higher absolute values.

#### Value

Returns a complex vector of function values.

euler\_heun 93

### Note

Copyright (c) 2001 Paul Godfrey for a Matlab version available on Mathwork's Matlab Central under BSD license.

z <- c(0, 0.5+1i, 1, 1i, 2+2i, -1, -2, -1-1i)
eta(z)</pre>
```

euler\_heun

Euler-Heun ODE Solver

# **Description**

Euler and Euler-Heun ODE solver.

# Usage

```
euler_heun(f, a, b, y0, n = 100, improved = TRUE, ...)
```

### **Arguments**

```
f function in the differential equation y' = f(x,y).

a, b start and end points of the interval.

y0 starting value at a.

n number of grid points.

improved logical; shall the Heun method be used; default TRUE.

additional parameters to be passed to the function.
```

### **Details**

euler\_heun is an integration method for ordinary differential equations using the simple Euler resp. the improved Euler-Heun Method.

#### Value

List with components t for grid (or 'time') points, and y the vector of predicted values at those grid points.

94 expint

expint

Exponential and Logarithmic Integral

## Description

The exponential integral functions E1 and Ei and the logarithmic integral Li.

The exponential integral is defined for x > 0 as

$$\int_{x}^{\infty} \frac{e^{-t}}{t} dt$$

and by analytic continuation in the complex plane. It can also be defined as the Cauchy principal value of the integral

$$\int_{-\infty}^{x} \frac{e^t}{t} dt$$

This is denoted as Ei(x) and the relationship between Ei and expint(x) for x real, x > 0 is as follows:

$$Ei(x) = -E1(-x) - i\pi$$

The logarithmic integral li(x) for real x, x > 0, is defined as

$$li(x) = \int_0^x \frac{dt}{log(t)}$$

and the Eulerian logarithmic integral as Li(x) = li(x) - li(2).

The integral Li approximates the prime number function  $\pi(n)$ , i.e., the number of primes below or equal to n (see the examples).

expint 95

### Usage

```
expint(x)
expint_E1(x)
expint_Ei(x)
li(x)
```

# Arguments

Х

vector of real or complex numbers.

### **Details**

For x in [-38,2] we use a series expansion, otherwise a continued fraction, see the references below, chapter 5.

#### Value

Returns a vector of real or complex numbers, the vectorized exponential integral, resp. the logarithmic integral.

#### Note

The logarithmic integral li(10^i)-li(2) is an approximation of the number of primes below 10^i, i.e., Pi(10^i), see "?primes".

96 expm

expm

Matrix Exponential

# **Description**

Computes the exponential of a matrix.

## Usage

```
expm(A, np = 128)
logm(A)
```

# **Arguments**

A numeric square matrix.

np number of points to use on the unit circle.

#### **Details**

For an analytic function f and a matrix A the expression f(A) can be computed by the Cauchy integral

$$f(A) = (2\pi i)^{-1} \int_{G} (zI - A)^{-1} f(z) dz$$

where G is a closed contour around the eigenvalues of A.

Here this is achieved by taking G to be a circle and approximating the integral by the trapezoid rule.

logm is a fake at the moment as it computes the matrix logarithm through taking the logarithm of its eigenvalues; will be replaced by an approach using Pade interpolation.

Another more accurate and more reliable approach for computing these functions can be found in the R package 'expm'.

#### Value

Matrix of the same size as A.

## Note

This approach could be used for other analytic functions, but a point to consider is which branch to take (e.g., for the logm function).

eye

Some Basic Matrices

# Description

Create basic matrices.

# Usage

```
eye(n, m = n)
ones(n, m = n)
zeros(n, m = n)
```

## **Arguments**

m, n

numeric scalars specifying size of the matrix

98 ezcontour,ezsurf,ezmesh

# Value

Matrix of size n x m. Defaults to a square matrix if m is missing.

No dropping of dimensions; if n = 1, still returns a matrix and not a vector.

### See Also

```
Diag,
```

# **Examples**

```

ones(3, 1)
zeros(1, 3)
```

```
ezcontour, ezsurf, ezmesh
```

Contour, Surface, and Mesh Plotter

# Description

Easy-to-use contour and 3-D surface resp mesh plotter.

# Usage

# **Arguments**

f	2-D function to be plotted, must accept (x,y) as a vector.
xlim, ylim	defines x- and y-ranges as intervals.
n	number of grid points in each direction.
col	colour of isolines lines, resp. the surface color.
filled	logical; shall the contour plot be
	parameters to be passed to the persp function.

ezplot 99

### **Details**

ezcontour generates a contour plot of the function f using contour (and image if filled=TRUE is chosen). If filled=TRUE is chosen, col should be a color scheme, the default is heat.colors(12). ezsurf resp. ezmesh generates a surface/mesh plot of the function f using persp.

The function f needs not be vectorized in any form.

### Value

Plots the function graph and invisibly returns NULL.

### Note

Mimicks Matlab functions of the same names; Matlab's ezcontourf can be generated with filled=TRUE.

### See Also

```
contour, image, persp
```

## **Examples**

```
## Not run:
f <- function(xy) {
    x <- xy[1]; y <- xy[2]
    3*(1-x)^2 * exp(-(x^2) - (y+1)^2) -
        10*(x/5 - x^3 - y^5) * exp(-x^2 - y^2) -
        1/3 * exp(-(x+1)^2 - y^2)
    }
ezcontour(f, col = "navy")
ezcontour(f, filled = TRUE)
ezmesh(f)
ezmesh(f)
ezmesh(f, col="lightblue", theta = -15, phi = 30)
## End(Not run)</pre>
```

ezplot

Easy Function Plot

## **Description**

Easy function plot w/o the need to define x, y coordinates.

100 ezplot

```
fill = FALSE, fillcol = "lightgray",
xlab = "x", ylab = "f (x)", main = "Function Plot", ...)
```

## **Arguments**

f	Function to be plotted.
interval	interval [a, b] to plot the function in
a, b	Left and right endpoint for the plot.
n	Number of points to plot.
col	Color of the function graph.
add	logical; shall the polt be added to an existing plot.
lty	line type; default 1.
lwd	line width; default 1.
marker	no. of markers to be added to the curve; defailt: none.
pch	poimt character; default circle.
grid	Logical; shall a grid be plotted?; default TRUE.
gridcol	Color of grid points.
fill	Logical; shall the area between function and axis be filled?; default: FALSE.
fillcol	Color of fill area.
xlab	Label on the x-axis.
ylab	Label on the y-axis.
main	Title of the plot
• • •	More parameters to be passed to plot.

# **Details**

Calculates the x, y coordinates of points to be plotted and calls the plot function.

If fill is TRUE, also calls the polygon function with the x,y coordinates in appropriate order.

If the no. of markers is greater than 2, this number of markers will be added to the curve, with equal distances measured along the curve.

## Value

Plots the function graph and invisibly returns NULL.

# Note

fplot is almost an alias for ezplot as all ez... will be replaced by MATLAB with function names f... in 2017.

ezplot should mimick the Matlab function of the same name, has more functionality, misses the possibility to plot several functions.

ezpolar 101

102 fact

fact

Factorial Function

# Description

Factorial for non-negative integers  $n \le 170$ .

# Usage

```
fact(n)
factorial2(n)
```

### **Arguments**

n

Vector of integers, for fact, resp. a single integer for factorial2.

#### **Details**

The factorial is computed by brute force; factorials for  $n \ge 171$  are not representable as 'double' anymore.

#### Value

fact returns the factorial of each element in n. If n < 0 the value is NaN, and for n > 170 it is Inf. Non-integers will be reduced to integers through floor(n).

factorial2 returns the product of all even resp. odd integers, depending on whether n is even or odd.

#### Note

The R core function factorial uses the gamma function, whose implementation is not accurate enough for larger input values.

#### See Also

```

# n! ~ sqrt(2*pi*n) * (n/e)^n

factorial2(8); factorial2(9); factorial2(10) # 384 945 3840
factorial(10) / factorial2(10) # => factorial2(9)
```

factors 103

factors

Prime Factors

# Description

Returns a vector containing the prime factors of n.

# Usage

```
factors(n)
```

## **Arguments**

n

nonnegative integer

### **Details**

Computes the prime factors of n in ascending order, each one as often as its multiplicity requires, such that n == prod(factors(n)).

The corresponding Matlab function is called 'factor', but because factors have a special meaning in R and the factor() function in R could not (or should not) be shadowed, the number theoretic function has been renamed here.

#### Value

Vector containing the prime factors of n.

### See Also

```
isprime, primes
```

```
## Not run:
  factors(1002001)  # 7 7 11 11 13 13

## End(Not run)
```

104 fderiv

fderiv	Numerical Differentiation	
--------	---------------------------	--

### **Description**

Numerical function differentiation for orders n=1..4 using finite difference approximations.

# Usage

```
fderiv(f, x, n = 1, h = 0, method = c("central", "forward", "backward"), ...)
```

## **Arguments**

f	function to be differentiated.
x	point(s) where differentiation will take place.
n	order of derivative, should only be between 1 and 8; for $n=0$ function values will be returned.
h	step size: if h=0 step size will be set automatically.
method	one of "central", "forward", or "backward".
	more variables to be passed to function f.

# **Details**

Derivatives are computed applying central difference formulas that stem from the Taylor series approximation. These formulas have a convergence rate of  $O(h^2)$ .

Use the 'forward' (right side) or 'backward' (left side) method if the function can only be computed or is only defined on one side. Otherwise, always use the central difference formulas.

Optimal step sizes depend on the accuracy the function can be computed with. Assuming internal functions with an accuracy 2.2e-16, appropriate step sizes might be 5e-6, 1e-4, 5e-4, 2.5e-3 for  $n=1,\ldots,4$  and precisions of about  $10^{-10}$ ,  $10^{-8}$ ,  $5*10^{-7}$ ,  $5*10^{-6}$  (at best).

For n>4 a recursion (or finite difference) formula will be applied, cd. the Wikipedia article on "finite difference".

#### Value

Vector of the same length as x.

#### Note

Numerical differentiation suffers from the conflict between round-off and truncation errors.

fibsearch

Fibonacci Search

### **Description**

Fibonacci search for function minimum.

## Usage

```
fibsearch(f, a, b, ..., endp = FALSE, tol = .Machine$double.eps^(1/2))
```

# **Arguments**

f	Function or its name as a string.
a, b	endpoints of the interval
endp	logical; shall the endpoints be considered as possible minima?
tol	absolute tolerance; default eps^(1/2).
	Additional arguments to be passed to f.

#### **Details**

Fibonacci search for a univariate function minimum in a bounded interval.

#### Value

Return a list with components xmin, fmin, the function value at the minimum, niter, the number of iterations done, and the estimated precision estim.prec

# **Examples**

```
f <- function(x) x * cos(0.1*exp(x)) * sin(0.1*pi*exp(x)) fibsearch(f, 0, 4, tol=10^-10) # $xmin = 3.24848329403424 optimize(f, c(0,4), tol=10^-10) # $minimum = 3.24848328971188
```

figure

Control Plot Devices (Matlab Style)

# Description

Open, activate, and close grahics devices.

# Usage

```
figure(figno, title = "")
```

# Arguments

figno (single) number of plot device.
title title of the plot device; not yet used.

# **Details**

The number of a graphics device cannot be 0 or 1. The function will work for the operating systems Mac OS, MS Windows, and most Linux systems.

If figno is negative and a graphics device with that number does exist, it will be closed.

### Value

No return value, except when a device of that number does not exist, in which case it returns a list of numbers of open graphics devices.

#### Note

Does not bring the activated graphics device in front.

#### See Also

```
dev.set,dev.off,dev.list

findintervals 107

# **Examples**

```
## Not run:
figure()
figure(-2)
## End(Not run)
```

findintervals

Find Interval Indices

# Description

Find indices i in vector xs such that either x=xs[i] or such that xs[i]<x<xs[i+1] or xs[i]>x>xs[i+1].

# Usage

```
findintervals(x, xs)
```

# Arguments

x single number.

xs numeric vector, not necessarily sorted.

# **Details**

Contrary to findInterval, the vector xs in findintervals need not be sorted.

#### Value

Vector of indices in 1..length(xs). If none is found, returns integer(0).

### Note

If x is equal to the last element in xs, the index length(xs) will also be returned.

```
xs <- zapsmall(sin(seq(0, 10*pi, len=100)))
findintervals(0, xs)
# 1 10 20 30 40 50 60 70 80 90 100</pre>
```

108 findmins

findmins

Find All Minima

#### **Description**

Finding all local(!) minima of a unvariate function in an interval by splitting the interval in many small subintervals.

## Usage

```
findmins(f, a, b, n = 100, tol = .Machine$double.eps^(2/3), ...)
```

### **Arguments**

f	functions whose minima shall be found.
a, b	endpoints of the interval.
n	number of subintervals to generate and search.
tol	has no effect at this moment.
	Additional parameters to be passed to the function.

#### **Details**

Local minima are found by looking for one minimum in each subinterval. It will be found by applying optimize to any two adjacent subinterval where the first slope is negative and the second one positive.

If the function is minimal on a whole subinterval, this will cause problems. If some minima are apparently not found, increase the number of subintervals.

Note that the endpoints of the interval will never be considered to be local minima. The function need not be vectorized.

#### Value

Numeric vector with the x-positions of all minima found in the interval.

# See Also

```
optimize
```

```
fun <- function(x) x * cos(0.1*exp(x)) * sin(0.1*pi*exp(x))
## Not run: ezplot(fun, 0, 5, n = 1001)

# If n is smaller, the rightmost minimum will not be found.
findmins(fun, 0, 5, n= 1000)
# 2.537727 3.248481 3.761840 4.023021 4.295831
# 4.455115 4.641481 4.756263 4.897461 4.987802</pre>
```

findpeaks 109

|--|

# Description

Find peaks (maxima) in a time series.

## Usage

## **Arguments**

X	numerical vector taken as a time series (no NAs allowed)
nups	minimum number of increasing steps before a peak is reached
ndowns	minimum number of decreasing steps after the peak
zero	can be '+', '-', or '0'; how to interprete succeeding steps of the same value: increasing, decreasing, or special
peakpat	define a peak as a regular pattern, such as the default pattern "[+]1,[-]1,"; if a pattern is provided, the parameters nups and ndowns are not taken into account
minpeakheight	the minimum (absolute) height a peak has to have to be recognized as such
minpeakdistance	
	the minimum distance (in indices) peaks have to have to be counted
threshold	the minimum
npeaks	the number of peaks to return
sortstr	logical; should the peaks be returned sorted in decreasing oreder of their maximum value

## **Details**

This function is quite general as it relies on regular patterns to determine where a peak is located, from beginning to end.

# Value

Returns a matrix where each row represents one peak found. The first column gives the height, the second the position/index where the maximum is reached, the third and forth the indices of where the peak begins and ends — in the sense of where the pattern starts and ends.

110 finds

## Note

On Matlab Central there are several realizations for finding peaks, for example "peakfinder", "peak-seek", or "peakdetect". And "findpeaks" is also the name of a function in the Matlab 'signal' toolbox.

The parameter names are taken from the "findpeaks" function in 'signal', but the implementation utilizing regular expressions is unique and fast.

## **Examples**

```
x <- seq(0, 1, len = 1024)
pos <- c(0.1, 0.13, 0.15, 0.23, 0.25, 0.40, 0.44, 0.65, 0.76, 0.78, 0.81)
hgt <- c(4, 5, 3, 4, 5, 4.2, 2.1, 4.3, 3.1, 5.1, 4.2)
wdt <- c(0.005, 0.005, 0.006, 0.01, 0.01, 0.03, 0.01, 0.01, 0.005, 0.008, 0.005)
pSignal <- numeric(length(x))
for (i in seq(along=pos)) {
   pSignal <- pSignal + hgt[i]/(1 + abs((x - pos[i])/wdt[i]))^4
}
findpeaks(pSignal, npeaks=3, threshold=4, sortstr=TRUE)

## Not run:
plot(pSignal, type="1", col="navy")
grid()
x <- findpeaks(pSignal, npeaks=3, threshold=4, sortstr=TRUE)
points(x[, 2], x[, 1], pch=20, col="maroon")
## End(Not run)</pre>
```

finds

find function (Matlab Style)

## **Description**

Finds indices of nonzero elements.

## Usage

finds(v)

## **Arguments**

٧

logical or numeric vector or array

## **Details**

Finds indices of true or nonzero elements of argument v; can be used with a logical expression.

findzeros 111

## Value

Indices of elements matching the expression x.

## **Examples**

```
finds(-3:3 >= 0)
finds(c(0, 1, 0, 2, 3))
```

findzeros

Find All Roots

# Description

Finding all roots of a unvariate function in an interval by splitting the interval in many small subintervals.

## Usage

```
findzeros(f, a, b, n = 100, tol = .Machinesdouble.eps^(2/3), ...)
```

## **Arguments**

f functions whose roots shall be found.

a, b endpoints of the interval.

n number of subintervals to generate and search.

tol tolerance for identifying zeros.

... Additional parameters to be passed to the function.

## **Details**

Roots, i.e. zeros in a subinterval will be found by applying uniroot to any subinterval where the sign of the function changes. The endpoints of the interval will be tested separately.

If the function points are both positive or negative and the slope in this interval is high enough, the minimum or maximum will be determined with optimize and checked for a possible zero.

The function need not be vectorized.

## Value

Numeric vector with the x-positions of all roots found in the interval.

## End(Not run)
```

fletcher\_powell

Fletcher-Powell Conjugate Gradient Minimization

## **Description**

Conjugate Gradient (CG) minimization through the Davidon-Fletcher-Powell approach for function minimization.

The Davidon-Fletcher-Powell (DFP) and the Broyden-Fletcher-Goldfarb-Shanno (BFGS) methods are the first quasi-Newton minimization methods developed. These methods differ only in some details; in general, the BFGS approach is more robust.

## Usage

## **Arguments**

x0	start value.
f	function to be minimized.
g	gradient function of f; if NULL, a numerical gradient will be calculated.
maxiter	max. number of iterations.
tol	relative tolerance, to be used as stopping rule.

fletcher\_powell 113

## **Details**

The starting point is Newton's method in the multivariate case, when the estimate of the minimum is updated by the following equation

$$x_{new} = x - H^{-1}(x)grad(g)(x)$$

where H is the Hessian and grad the gradient.

The basic idea is to generate a sequence of good approximations to the inverse Hessian matrix, in such a way that the approximations are again positive definite.

## Value

List with following components:

xmin minimum solution found.fmin value of f at minimum.niter number of iterations performed.

#### Note

Used some Matlab code as described in the book "Applied Numerical Analysis Using Matlab" by L. V.Fausett.

#### References

114 flipdim

flipdim

Matrix Flipping (Matlab Style)

# Description

Flip matrices up and down or left and right; or circulating indices per dimension.

## Usage

```
flipdim(a, dim)
flipud(a)
fliplr(a)
circshift(a, sz)
```

## **Arguments**

```
a numeric or complex matrix
dim flipping dimension; can only be 1 (default) or 2
```

sz integer vector of length 1 or 2.

# **Details**

flipdim will flip a matrix along the dim dimension, where dim=1 means flipping rows, and dim=2 flipping the columns.

```
flipud and fliplr are simply shortcuts for flipdim(a, 1) resp. flipdim(a, 2). circshift(a, sz) circulates each dimension (should be applicable to arrays).
```

## Value

the original matrix somehow flipped or circularly shifted.

```
a <- matrix(1:12, nrow=3, ncol=4, byrow=TRUE)
flipud(a)
fliplr(a)

circshift(a, c(1, -1))
v <- 1:10
circshift(v, 5)</pre>
```

fminbnd 115

## Description

Find minimum of single-variable function on fixed interval.

## Usage

#### Arguments

f function whose minimum or maximum is to be found.

a, b endpoints of the interval to be searched.

maxiter maximal number of iterations.

maximum logical; shall maximum or minimum be found; default FALSE.

tol relative tolerance; left over for compatibility.

rel.tol, abs.tol

relative and absolute tolerance.

... additional variables to be passed to the function.

## **Details**

fminbnd finds the minimum of a function of one variable within a fixed interval. It applies Brent's algorithm, based on golden section search and parabolic interpolation.

fminbnd may only give local solutions. fminbnd never evaluates f at the endpoints.

## Value

List with

xmin location of the minimum resp. maximum.

fmin function value at the optimum.

niter number of iterations used.

estim.prec estimated precision.

### Note

fminbnd mimics the Matlab function of the same name.

## **Examples**

fmincon

Minimize Nonlinear Constrained Multivariable Function.

## **Description**

Find minimum of multivariable functions with nonlinear constraints.

## Usage

```
fmincon(x0, fn, gr = NULL, ..., method = "SQP",
    A = NULL, b = NULL, Aeq = NULL, beq = NULL,
    lb = NULL, ub = NULL, hin = NULL, heq = NULL,
    tol = 1e-06, maxfeval = 10000, maxiter = 5000)
```

# Arguments

x0	starting point.
fn	objective function to be minimized.
gr	gradient function of the objective; not used for SQP method.
	additional parameters to be passed to the function.
method	method options 'SQP', 'auglag'; only 'SQP is implemented.
A, b	linear ineqality constraints of the form A $x \le b$ .
Aeq, beq	linear eqality constraints of the form $Aeq x = beq$ .
lb, ub	bounds constraints of the form $lb \le x \le ub$ .
hin	nonlinear inequality constraints of the form $hin(x) \le 0$ .
heq	nonlinear equality constraints of the form $heq(x) = 0$ .

fmincon 117

tol relative tolerance.

maxiter maximum number of iterations.

maxfeval maximum number of function evaluations.

## **Details**

Wraps the function solnl in the 'NlcOptim' package. The underlying method is a Squential Quadratic Programming (SQP) approach.

Constraints can be defined in different ways, as linear constraints in matrix form, as nonlinear functions, or as bounds constraints.

#### Value

List with the following components:

par the best minimum found.

value function value at the minimum.

convergence integer indicating the terminating situation.

info parameter list describing the final situation.

#### Note

fmincon mimics the Matlab function of the same name.

fminsearch

Derivative-free Nonlinear Function Minimization

# **Description**

Find minimum of multivariable functions using derivative-free methods.

## Usage

## **Arguments**

fn function whose minimum or maximum is to be found.

x0 point considered near to the optimum.

. . . additional variables to be passed to the function.

lower, upper lower and upper bounds constraints.

method "Nelder-Mead" (default) or "Hooke-Jeeves"; can be abbreviated.

minimize logical; shall a minimum or a maximum be found.

maxiter maximal number of iterations

tol relative tolerance.

## **Details**

fminsearch finds the minimum of a nonlinear scalar multivariable function, starting at an initial estimate and returning a value x that is a local minimizer of the function. With minimize=FALSE it searches for a maximum, by default for a (local) minimum.

As methods/solvers "Nelder-Mead" and "Hooke-Jeeves" are available. Only Hooke-Jeeves can handle bounds constraints. For nonlinear constraints see fmincon, and for methods using gradients see fminunc.

Important: fminsearch may only give local solutions.

fminunc 119

## Value

List with

xopt location of the location of minimum resp. maximum.

fmin function value at the optimum.

count number of function calls.

convergence info about convergence: not used at the moment.

info special information from the solver.

## **Examples**

fminunc

Minimize Unconstrained Multivariable Function

# **Description**

Find minimum of unconstrained multivariable functions.

## Usage

120 fminunc

### **Arguments**

x0	starting point.
fn	objective function to be minimized.
gr	gradient function of the objective.
	additional parameters to be passed to the function.
tol	relative tolerance.

maximum number of iterations. maxiter

maxfeval maximum number of function evaluations.

## **Details**

The method used here for unconstrained minimization is a variant of a "variable metric" resp. quasi-Newton approach.

## Value

List with the following components:

the best minimum found. par function value at the minimum. value number of function and gradient calls. counts integer indicating the terminating situation. convergence

description of the final situation. message

### Note

fminunc mimics the Matlab function of the same name.

## Author(s)

The "variable metric" code provided by John Nash (package Rymmin), stripped-down version by Hans W. Borchers.

## References

## xmin: c(-0.6691, 0.0000); fmin: -0.4052
```

fnorm 121

|--|

## **Description**

The fnorm function calculates several different types of function norms for depending on the argument p.

# Usage

```
fnorm(f, g, x1, x2, p = 2, npoints = 100)
```

# **Arguments**

f, g functions given by name or string.

x1, x2 endpoints of the interval.

p Numeric scalar or Inf, -Inf; default is 2.

npoints number of points to be considered in the interval.

## **Details**

fnorm returns a scalar that gives some measure of the distance of two functions f and g on the interval [x1, x2].

It takes npoints equidistant points in the interval, computes the function values for f and g and applies Norm to their difference.

Especially p=Inf returns the maximum norm, while fnorm(f,g,x1,x2,p = 1,npoints) / npoints would return some estimate of the mean distance.

## Value

Numeric scalar (or Inf), or NA if one of these functions returns NA.

## Note

Another kind of 'mean' distance could be calculated by integrating the difference f-g and dividing through the length of the interval.

#### See Also

Norm

122 fornberg

## **Examples**

```
xp <- seq(-1, 1, length.out = 6)
yp <- runge(xp)
p5 <- polyfit(xp, yp, 5)
f5 <- function(x) polyval(p5, x)
fnorm(runge, f5, -1, 1, p = Inf)  #=> 0.4303246
fnorm(runge, f5, -1, 1, p = Inf, npoints = 1000) #=> 0.4326690

# Compute mean distance using fnorm:
fnorm(runge, f5, -1, 1, p = 1, 1000) / 1000 #=> 0.1094193

# Compute mean distance by integration:
fn <- function(x) abs(runge(x) - f5(x))
integrate(fn, -1, 1)$value / 2 #=> 0.1095285
```

fornberg

Fornberg's Finite Difference Approximation

## **Description**

Finite difference approximation using Fornberg's method for the derivatives of order 1 to k based on irregulat grid values.

#### **Usage**

```
fornberg(x, y, xs, k = 1)
```

## **Arguments**

x grid points on the x-axis, must be distinct.
y discrete values of the function at the grid points.
xs point at which to approximate (not vectorized).
k order of derivative, k<=length(x)-1 required.

# **Details**

Compute coefficients for finite difference approximation for the derivative of order k at xs based on grid values at points in x. For k=0 this will evaluate the interpolating polynomial itself, but call it with k=1.

## Value

Returns a matrix of size (length(xs)), where the (k+1)-th column gives the value of the k-th derivative. Especially the first column returns the polynomial interpolation of the function.

fprintf 123

## Note

Fornberg's method is considered to be numerically more stable than applying Vandermonde's matrix.

fprintf

Formatted Printing (Matlab style)

## **Description**

Formatted printing to stdout or a file.

## Usage

```
fprintf(fmt, ..., file = "", append = FALSE)
```

### **Arguments**

fmt a character vector of format strings. . . . values passed to the format string.

file a connection or a character string naming the file to print to; default is "" which

means standard output.

append logical; shall the output be appended to the file; default is FALSE.

### **Details**

fprintf applies the format string fmt to all input data ... and writes the result to standard output or a file. The usual C-style string formatting commands are used-

124 fractalcurve

#### Value

Returns invisibly the number of bytes printed (using nchar).

#### See Also

```
sprintf
```

## **Examples**

```
## Examples:

}</pre>
```

fractalcurve

Fractal Curves

## **Description**

Generates the following fractal curves: Dragon Curve, Gosper Flowsnake Curve, Hexagon Molecule Curve, Hilbert Curve, Koch Snowflake Curve, Sierpinski Arrowhead Curve, Sierpinski (Cross) Curve, Sierpinski Triangle Curve.

### Usage

# Arguments

n integer, the 'order' of the curve
which character string, which curve to cumpute.

### Details

The Hilbert curve is a continuous curve in the plane with 4<sup>N</sup> points.

The Sierpinski (cross) curve is a closed curve in the plane with 4^(N+1)+1 points.

His arrowhead curve is a continuous curve in the plane with  $3^N+1$  points, and his triangle curve is a closed curve in the plane with  $2*3^N+2$  points.

The Koch snowflake curve is a closed curve in the plane with 3\*2^N+1 points.

The dragon curve is a continuous curve in the plane with  $2^{(N+1)}$  points.

The flowsnake curve is a continuous curve in the plane with 7^N+1 points.

The hexagon molecule curve is a closed curve in the plane with 6\*3^N+1 points.

fractalcurve 125

#### Value

Returns a list with x,y the x- resp. y-coordinates of the generated points describing the fractal curve

fresnelS/C

Fresnel Integrals

## **Description**

(Normalized) Fresnel integrals S(x) and C(x)

## Usage

```
fresnelS(x) fresnelC(x)
```

## **Arguments**

Х

numeric vector.

## **Details**

The normalized Fresnel integrals are defined as

$$S(x) = \int_0^x \sin(\pi/2t^2)dt$$

$$C(x) = \int_0^x \cos(\pi/2t^2)dt$$

This program computes the Fresnel integrals S(x) and C(x) using Fortran code by Zhang and Jin. The accuracy is almost up to Machine precision.

The functions are not (yet) truly vectorized, but use a call to 'apply'. The underlying function fresnel (not exported) computes single values of S(x) and C(x) at the same time.

## Value

Numeric vector of function values.

## Note

Copyright (c) 1996 Zhang and Jin for the Fortran routines, converted to Matlab using the open source project 'f2matlab' by Ben Barrowes, posted to MatlabCentral in 2004, and then translated to R by Hans W. Borchers.

fsolve

Solve System of Nonlinear Equations

## Description

Solve a system of m nonlinear equations of n variables.

128 fsolve

## Usage

```
fsolve(f, x0, J = NULL,
maxiter = 100, tol = .Machine$double.eps^(0.5), ...)
```

## **Arguments**

f function describing the system of equations.

x0 point near to the root.

J Jacobian function of f, or NULL.

maxiter maximum number of iterations in gaussNewton.

tol tolerance to be used in Gauss-Newton.

## **Details**

fsolve tries to solve the components of function f simultaneously and uses the Gauss-Newton method with numerical gradient and Jacobian. If m = n, it uses broyden. Not applicable for univariate root finding.

additional variables to be passed to the function.

#### Value

List with

x location of the solution.fval function value at the solution.

## Note

fsolve mimics the Matlab function of the same name.

#### References

fzero

Root Finding Algorithm

# Description

Find root of continuous function of one variable.

# Usage

```
fzero(fun, x, maxiter = 500, tol = 1e-12, ...)
```

## **Arguments**

fun function whose root is sought.

x a point near the root or an interval giving end points.

maxiter maximum number of iterations.

tol relative tolerance.

... additional arguments to be passed to the function.

## **Details**

fzero tries to find a zero of f near x, if x is a scalar. Expands the interval until different signs are found at the endpoints or the maximum number of iterations is exceeded. If x is a vector of length two, fzero assumes x is an interval where the sign of x[1] differs from the sign of x[1]. An error occurs if this is not the case.

"This is essentially the ACM algorithm 748. The structure of the algorithm has been transformed non-trivially: it implement here a FSM version using one interior point determination and one bracketing per iteration, thus reducing the number of temporary variables and simplifying the structure."

This approach will not find zeroes of quadratic order.

#### Value

fzero returns a list with

x location of the root.

fval function value at the root.

130 fzsolve

## Note

fzero mimics the Matlab function of the same name, but is translated from Octave's fzero function, copyrighted (c) 2009 by Jaroslav Hajek.

fzsolve

Complex Root Finding

## **Description**

Find the root of a complex function

## Usage

```
fzsolve(fz, z0)
```

#### **Arguments**

fz complex(-analytic) function.

z0 complex point near the assumed root.

# **Details**

fzsolve tries to find the root of the complex and relatively smooth (i.e., analytic) function near a starting point.

The function is considered as real function  $R^2 --> R^2$  and the newtonsys function is applied.

### Value

Complex point with sufficiently small function value.

## See Also

newtonsys

gammainc 131

## **Examples**

```
fz <- function(z) sin(z)^2 + sqrt(z) - log(z)
fzsolve(fz, 1+1i)
# 0.2555197+0.8948303i</pre>
```

gammainc

Incomplete Gamma Function

## Description

Lower and upper incomplete gamma function.

## Usage

```
gammainc(x, a)
incgam(x, a)
```

## **Arguments**

x positive real number.

a real number.

# **Details**

gamma inc computes the lower and upper incomplete gamma function, including the regularized gamma function. The lower and upper incomplete gamma functions are defined as

$$\gamma(x,a) = \int_0^x e^{-t} t^{a-1} dt$$

and

$$\Gamma(x,a) = \int_{x}^{\infty} e^{-t} t^{a-1} dt$$

while the regularized incomplete gamma function is  $\gamma(x,a)/\Gamma(a)$ .

incgam (a name used in Pari/GP) computes the upper incomplete gamma function alone, applying the R function pgamma. The accuracy is thus much higher. It works for a >= -1, for even smaller values a recursion will give the result.

## Value

gammainc returns a list with the values of the lower, the upper, and regularized lower incomplete gamma function. incgam only returns the value of the incomplete upper gamma function.

## Note

Directly converting Fortran code is often easier than translating Matlab code generated with f2matlab.

incgam(3, 0.5); incgam(3, -0.5)
```

gammaz

Complex Gamma Function

## **Description**

Gamma function valid in the entire complex plane.

## Usage

```
gammaz(z)
```

## **Arguments**

z

Real or complex number or a numeric or complex vector.

# Details

Computes the Gamma function for complex arguments using the Lanczos series approximation.

Accuracy is 15 significant digits along the real axis and 13 significant digits elsewhere.

To compute the logarithmic Gamma function use log(gammaz(z)).

## Value

Returns a complex vector of function values.

#### Note

Copyright (c) 2001 Paul Godfrey for a Matlab version available on Mathwork's Matlab Central under BSD license.

Numerical Recipes used a 7 terms formula for a less effective approximation.

gaussHermite

Gauss-Hermite Quadrature Formula

## **Description**

Nodes and weights for the n-point Gauss-Hermite quadrature formula.

## Usage

```
gaussHermite(n)
```

## **Arguments**

n

Number of nodes in the interval <code>]-Inf,Inf[</code>.

#### **Details**

Gauss-Hermite quadrature is used for integrating functions of the form

$$\int_{-\infty}^{\infty} f(x)e^{-x^2}dx$$

over the infinite interval  $]-\infty,\infty[.$ 

x and w are obtained from a tridiagonal eigenvalue problem. The value of such an integral is then sum(w\*f(x)).

### Value

List with components x, the nodes or points in]-Inf, Inf[, and w, the weights applied at these nodes.

134 gaussLaguerre

## Note

The basic quadrature rules are well known and can, e. g., be found in Gautschi (2004) — and explicit Matlab realizations in Trefethen (2000). These procedures have also been implemented in Matlab by Geert Van Damme, see his entries at MatlabCentral since 2010.

## References

## **Examples**

```
cc <- gaussHermite(17)
# Integrate exp(-x^2) from -Inf to Inf
sum(cc$w)  #=> 1.77245385090552 == sqrt(pi)
# Integrate x^2 exp(-x^2)
sum(cc$w * cc$x^2)  #=> 0.88622692545276 == sqrt(pi) /2
# Integrate cos(x) * exp(-x^2)
sum(cc$w * cos(cc$x))  #=> 1.38038844704314 == sqrt(pi)/exp(1)^0.25
```

gaussLaguerre

Gauss-Laguerre Quadrature Formula

## **Description**

Nodes and weights for the n-point Gauss-Laguerre quadrature formula.

### **Usage**

```
gaussLaguerre(n, a = 0)
```

## Arguments

n Number of nodes in the interval [0, Inf[.

a exponent of x in the integrand: must be greater or equal to 0, otherwise the integral would not converge.

gaussLaguerre 135

## **Details**

Gauss-Laguerre quadrature is used for integrating functions of the form

$$\int_0^\infty f(x)x^a e^{-x} dx$$

over the infinite interval  $]0, \infty[$ .

x and w are obtained from a tridiagonal eigenvalue problem. The value of such an integral is then sum(w\*f(x)).

## Value

List with components x, the nodes or points in [0, Inf[, and w, the weights applied at these nodes.

#### Note

The basic quadrature rules are well known and can, e. g., be found in Gautschi (2004) — and explicit Matlab realizations in Trefethen (2000). These procedures have also been implemented in Matlab by Geert Van Damme, see his entries at MatlabCentral since 2010.

gaussLegendre

Gauss-Legendre Quadrature Formula

## **Description**

Nodes and weights for the n-point Gauss-Legendre quadrature formula.

# Usage

```
gaussLegendre(n, a, b)
```

## **Arguments**

- n Number of nodes in the interval [a,b].
- a, b lower and upper limit of the integral; must be finite.

## **Details**

x and w are obtained from a tridiagonal eigenvalue problem.

## Value

List with components x, the nodes or points in [a, b], and w, the weights applied at these nodes.

## Note

Gauss quadrature is not suitable for functions with singularities.

#### References

drop(cc$w %*% matrix(f(cc$x), ncol = 3))  # c(2/pi, exp(1) - 1, 2*log(2) - 1)
# absolute error < 1e-15</pre>
```

gaussNewton

Gauss-Newton Function Minimization

## **Description**

Gauss-Newton method of minimizing a term  $f_1(x)^2 + \ldots + f_m(x)^2$  or F'F where  $F = (f_1, \ldots, f_m)$  is a multivariate function of n variables, not necessarily n = m.

#### **Usage**

## **Arguments**

Ffun	m functions of n variables.
Jfun	function returning the Jacobian matrix of Ffun; if NULL, the default, the Jacobian will be computed numerically. The gradient of f will be computed internally from the Jacobian (i.e., cannot be supplied).
x0	Numeric vector of length n.
maxiter	Maximum number of iterations.
tol	Tolerance, relative accuracy.
	Additional parameters to be passed to f.

## Details

Solves the system of equations applying the Gauss-Newton's method. It is especially designed for minimizing a sum-of-squares of functions and can be used to find a common zero of several function.

This algorithm is described in detail in the textbook by Antoniou and Lu, incl. different ways to modify and remedy the Hessian if not being positive definite. Here, the approach by Goldfeld, Quandt and Trotter is used, and the hessian modified by the Matthews and Davies algorithm if still not invertible.

To accelerate the iteration, an inexact linesearch is applied.

138 gaussNewton

## Value

List with components:

xs the minimum or root found so far,

fs the square root of sum of squares of the values of f,

iter the number of iterations needed, and

relerr the absoulte distance between the last two solutions.

## Note

If n=m then directly applying the newtonsys function might be a better alternative.

gauss\_kronrod

Gauss-Kronrod Quadrature

## **Description**

Simple Gaussian-Kronrod quadrature formula.

## Usage

```
gauss_kronrod(f, a, b, ...)
```

## **Arguments**

```
f function to be integrated.
a, b end points of the interval.
... variables to be passed to the function.
```

## **Details**

Gaussian quadrature of degree 7 with Gauss-Kronrod of degree 15 for error estimation, the quadQK15 procedure in the QUADPACK library.

## Value

List of value and relative error.

## Note

The function needs to be vectorized (though this could easily be changed), but the function does not need to be defined at the end points.

## References

Fausett, L. V. (2007). Applied Numerical Analysis Using Matlab. Second edition, Prentice Hall.

140 gcd, lcm

gcd, 1cm

GCD and LCM Integer Functions

## **Description**

Greatest common divisor and least common multiple

## Usage

```
gcd(a, b, extended = FALSE)
Lcm(a, b)
```

## **Arguments**

a, b vectors of integers.

extended logical; if TRUE the extended Euclidean algorithm will be applied.

## **Details**

Computation based on the extended Euclidean algorithm.

If both a and b are vectors of the same length, the greatest common divisor/lowest common multiple will be computed elementwise. If one is a vektor, the other a scalar, the scalar will be replicated to the same length.

### Value

A numeric (integer) value or vector of integers. Or a list of three vectors named c,d,g, g containing the greatest common divisors, such that

```
g = c * a + d * b.
```

# Note

The following relation is always true:

```
n * m = gcd(n,m) * lcm(n,m)
```

## See Also

```

geomean, harmmean 141

geomean, harmmean

Geometric and Harmonic Mean (Matlab Style)

# Description

Geometric and harmonic mean along a dimension of a vector, matrix, or array. trimmean is almost the same as mean in R.

# Usage

```
geomean(x, dim = 1)
harmmean(x, dim = 1)
trimmean(x, percent = 0)
```

## **Arguments**

x numeric vector, matrix, or array.

dim dimension along which to take the mean; dim=1 means along columns, dim=2

along rows, the result will still be a row vector, not a column vector as in Matlab.

percent percentage, between 0 and 100, of trimmed values.

## **Details**

trimmean does not call mean with the trim option, but rather calculates k<-round(n\*percent/100/2) and leaves out k values at the beginning and end of the sorted x vector (or row or column of a matrix).

## Value

Returns a scalar or vector (or array) of geometric or harmonic means: For dim=1 the mean of columns, dim=2 the mean of rows, etc.

## Note

To have an exact analogue of mean(x) in Matlab, apply trimmean(x).

## See Also

mean

142 geo\_median

## **Examples**

geo\_median

Geometric Median

## **Description**

Compute the "geometric median" of points in n-dimensional space, that is the point with the least sum of (Euclidean) distances to all these points.

## Usage

```
geo_median(P, tol = 1e-07, maxiter = 200)
```

## **Arguments**

P matrix of points, x\_i-coordinates in the ith column.

tol relative tolerance.

maxiter maximum number of iterations.

## Details

The task is solved applying an iterative process, known as Weiszfeld's algorithm. The solution is unique whenever the points are not collinear.

If the dimension is 1 (one column), the median will be returned.

### Value

Returns a list with components p the coordinates of the solution point, d the sum of distances to all the sample points, reltol the relative tolerance of the iterative process, and niter the number of iterations.

## Note

This is also known as the "1-median problem" and can be generalized to the "k-median problem" for k cluster centers; see kcca in the 'flexclust' package.

```

gmres

Generalized Minimal Residual Method

## **Description**

gmres(A,b) attempts to solve the system of linear equations A\*x=b for x.

## Usage

```
gmres(A, b, x0 = rep(0, length(b)),
errtol = 1e-6, kmax = length(b)+1, reorth = 1)
```

## **Arguments**

A square matrix.

b numerical vector or column vector.

x0 initial iterate.

errtol relative residual reduction factor.

kmax maximum number of iterations

reorth reorthogonalization method, see Details.

## **Details**

Iterative method for the numerical solution of a system of linear equations. The method approximates the solution by the vector in a Krylov subspace with minimal residual. The Arnoldi iteration is used to find this vector.

Reorthogonalization method:

- 1 Brown/Hindmarsh condition (default)
- 2 Never reorthogonalize (not recommended)
- 3 Always reorthogonalize (not cheap!)

golden\_ratio 145

# Value

Returns a list with components x the solution, error the vector of residual norms, and niter the number of iterations.

# Author(s)

Based on Matlab code from C. T. Kelley's book, see references.

golden\_ratio

Golden Ratio Search

# **Description**

Golden Ratio search for a univariate function minimum in a bounded interval.

146 grad

## Usage

```
golden_ratio(f, a, b, ..., maxiter = 100, tol = .Machine$double.eps^0.5)
```

### **Arguments**

f Function or its name as a string.

a, b endpoints of the interval.

maxiter maximum number of iterations.

tol absolute tolerance; default sqrt(eps).

... Additional arguments to be passed to f.

### **Details**

'Golden ratio' search for a univariate function minimum in a bounded interval.

#### Value

Return a list with components xmin, fmin, the function value at the minimum, niter, the number of iterations done, and the estimated precision estim.prec

# See Also

uniroot

# **Examples**

```
f \leftarrow function(x) \ x * cos(0.1*exp(x)) * sin(0.1*pi*exp(x))

golden_ratio(f, 0, 4, tol=10^-10) \# xmin = 3.24848329206212

optimize(f, c(0,4), tol=10^-10) \# xminimum = 3.24848328971188
```

grad

Numerical Gradient

# **Description**

Numerical function gradient.

# Usage

```
grad(f, x0, heps = .Machine$double.eps^(1/3), ...)
```

# **Arguments**

```
f function of several variables.

x0 point where the gradient is to build.

heps step size.

... more variables to be passed to function f.
```

gradient 147

## **Details**

Computes the gradient

$$(\frac{\partial f}{\partial x_1}, \dots, \frac{\partial f}{\partial x_n})$$

numerically using the "central difference formula".

### Value

Vector of the same length as x0.

#### References

Mathews, J. H., and K. D. Fink (1999). Numerical Methods Using Matlab. Third Edition, Prentice Hall.

fderiv

# **Examples**

```
f <- function(u) {
    x <- u[1]; y <- u[2]; z <- u[3]
    return(x^3 + y^2 + z^2 +12*x*y + 2*z)
}
x0 <- c(1,1,1)
grad(f, x0)  # 15 14 4  # direction of steepest descent
sum(grad(f, x0) * c(1, -1, 0))  # 1 , directional derivative
f <- function(x) x[1]^2 + x[2]^2
grad(f, c(0,0))  # 0 0 , i.e. a local optimum</pre>
```

gradient

Discrete Gradient (Matlab Style)

# Description

Discrete numerical gradient.

# Usage

```
gradient(F, h1 = 1, h2 = 1)
```

148 gradient

# Arguments

F	vector of function values, or a matrix of values of a function of two variables.
h1	x-coordinates of grid points, or one value for the difference between grid points in x-direction.
h2	y-coordinates of grid points, or one value for the difference between grid points in y-direction.

## **Details**

Returns the numerical gradient of a vector or matrix as a vector or matrix of discrete slopes in x-(i.e., the differences in horizontal direction) and slopes in y-direction (the differences in vertical direction).

A single spacing value, h, specifies the spacing between points in every direction, where the points are assumed equally spaced.

## Value

If F is a vector, one gradient vector will be returned.

If F is a matrix, a list with two components will be returned:

X numerical gradient/slope in x-direction.Y numerical gradient/slope in x-direction.

where each matrix is of the same size as F.

## Note

TODO: If h2 is missing, it will not automatically be adapted.

quiver(X, Y, grX, grY, scale = 0.2, col="blue")

## End(Not run)</pre>
```

gramSchmidt

Gram-Schmidt

# **Description**

Modified Gram-Schmidt Process

# Usage

```
gramSchmidt(A, tol = .Machine$double.eps^0.5)
```

# **Arguments**

A numeric matrix with nrow(A)>=ncol(A).
tol numerical tolerance for being equal to zero.

## **Details**

The modified Gram-Schmidt process uses the classical orthogonalization process to generate step by step an orthonoral basis of a vector space. The modified Gram-Schmidt iteration uses orthogonal projectors in order ro make the process numerically more stable.

### Value

List with two matrices Q and R, Q orthonormal and R upper triangular, such that A=Q%\*%R.

 Q %*% R # = A
```

hadamard

Hadamard Matrix

# **Description**

Generate Hadamard matrix of a certain size.

# Usage

hadamard(n)

# **Arguments**

n

An integer of the form 2<sup>e</sup>, 12\*2<sup>e</sup>, or 20\*2<sup>e</sup>

## **Details**

An n-by-n Hadamard matrix with n>2 exists only if rem(n, 4)=0. This function handles only the cases where n, n/12, or n/20 is a power of 2.

# Value

Matrix of size n-by-n of orthogonal columns consisting of 1 and -1 only.

## Note

Hadamard matrices have applications in combinatorics, signal processing, and numerical analysis.

halley 151

hэ	1	1	۵	٠
Ha	т	т	e	١

Halley's Root Finding Mathod

# Description

Finding roots of univariate functions using the Halley method.

# Usage

```
halley(fun, x0, maxiter = 500, tol = 1e-08, ...)
```

## **Arguments**

fun	function whose root is to be found.
x0	starting value for the iteration.
maxiter	maximum number of iterations.
tol	absolute tolerance; default eps^(1/2)
	additional arguments to be passed to the function.

## **Details**

Well known root finding algorithms for real, univariate, continuous functions; the second derivative must be smooth, i.e. continuous. The first and second derivative are computed numerically.

## Value

Return a list with components root, f.root, the function value at the found root, iter, the number of iterations done, and the estimated precision estim.prec

Hampel Filter

# **Description**

Median absolute deviation (MAD) outlier in Time Series

## Usage

```
hampel(x, k, t0 = 3)
```

## **Arguments**

x numeric vector representing a time series

k window length 2\*k+1 in indices

threshold, default is 3 (Pearson's rule), see below.

#### **Details**

The 'median absolute deviation' computation is done in the [-k...k] vicinity of each point at least k steps away from the end points of the interval. At the lower and upper end the time series values are preserved.

A high threshold makes the filter more forgiving, a low one will declare more points to be outliers. t0<-3 (the default) corresponds to Ron Pearson's 3 sigma edit rule, t0<-0 to John Tukey's median filter.

### Value

Returning a list L with L\$y the corrected time series and L\$ind the indices of outliers in the 'median absolut deviation' sense.

# Note

Don't take the expression *outlier* too serious. It's just a hint to values in the time series that appear to be unusual in the vicinity of their neighbors under a normal distribution assumption.

hankel

Hankel Matrix

# **Description**

Generate Hankel matrix from column and row vector

# Usage

```
hankel(a, b)
```

# Arguments

- a vector that will be the first column
- b vector that if present will form the last row.

### **Details**

hankel(a) returns the square Hankel matrix whose first column is a and whose elements are zero below the secondary diagonal. (I.e.: b may be missing.)

hankel(a,b) returns a Hankel matrix whose first column is a and whose last row is b. If the first element of b differs from the last element of a it is overwritten by this one.

#### Value

```
matrix of size (length(a),length(b))
```

# See Also

```
hankel(1:5, 5:1)
```

154 hausdorff\_dist

 $hausdorff\_dist$ 

Hausdorff Distance

# Description

Hausdorff distance (aka Hausdorff dimension)

# Usage

```
hausdorff_dist(P, Q)
```

## **Arguments**

P, Q

numerical matrices, representing points in an m-dim. space.

#### **Details**

Calculates the Hausdorff Distance between two sets of points, P and Q. Sets P and Q must be matrices with the same number of columns (dimensions).

The 'directional' Hausdorff distance (dhd) is defined as:

```
dhd(P,Q) = max p in P [min q in Q [||p-q||]]
```

Intuitively dhd finds the point p from the set P that is farthest from any point in Q and measures the distance from p to its nearest neighbor in Q. The Hausdorff Distance is defined as  $\max(\text{dhd}(P,Q),\text{dhd}(Q,P))$ .

#### Value

A single scalar, the Hausdorff distance (dimension).

haversine 155

haversine

Haversine Formula

## **Description**

Haversine formula to calculate the arc distance between two points on earth (i.e., along a great circle).

## Usage

```
haversine(loc1, loc2, R = 6371.0)
```

## **Arguments**

loc1, loc2 Locations on earth; for format see Details.

R Average earth radius R = 6371 km, can be changed on input.

## **Details**

The Haversine formula is more robust for the calculating the distance as with the spherical cosine formula. The user may want to assume a slightly different earth radius, so this can be provided as input.

The location can be input in two different formats, as latitude and longitude in a character string, e.g. for Frankfurt airport as '50 02 00N, 08 34 14E', or as a numerical two-vector in degrees (not radians).

Here for latitude 'N' and 'S' stand for North and South, and for longitude 'E' or 'W' stand for East and West. For the degrees format, South and West must be negative.

These two formats can be mixed.

#### Value

Returns the distance in km.

## Author(s)

Hans W. Borchers

### References

Entry 'Great\_circle\_distance' in Wikipedia.

FRA = '50 02 00N, 08 34 14E' # Frankfurt Airport
ORD = '41 58 43N, 87 54 17W' # Chicago O'Hare Interntl. Airport
fra <- c(50+2/60, 8+34/60+14/3600)
ord <- c(41+58/60+43/3600, -(87+54/60+17/3600))

dis <- haversine(FRA, ORD) # 6971.059 km
fprintf('Flight distance Frankfurt-Chicago is %8.3f km.\n', dis)

dis <- haversine(fra, ord)
fprintf('Flight distance Frankfurt-Chicago is %8.3f km.\n', dis)
```

hessenberg

Hessenberg Matrix

## **Description**

Generates the Hessenberg matrix for A.

## Usage

hessenberg(A)

## **Arguments**

Α

square matrix

## **Details**

An (upper) Hessenberg matrix has zero entries below the first subdiagonal.

The function generates a Hessenberg matrix H and a unitary matrix P (a similarity transformation) such that A = P \* H \* t(P).

The Hessenberg matrix has the same eigenvalues. If A is symmetric, its Hessenberg form will be a tridiagonal matrix.

## Value

Returns a list with two elements,

H the upper Hessenberg Form of matrix A.

H a unitary matrix.

histc

Histogram Count (Matlab style)

## **Description**

Histogram-like counting.

# Usage

```
histc(x, edges)
```

# **Arguments**

x numeric vector or matrix.

edges numeric vector of grid points, must be monotonically non-decreasing.

## **Details**

n = histc(x, edges) counts the number of values in vector x that fall between the elements in the edges vector (which must contain monotonically nondecreasing values). n is a length(edges) vector containing these counts.

If x is a matrix then cnt and bin are matrices too, and

```
for (j in (1:n)) cnt[k,j] <-sum(bin[,j] == k)
```

### Value

returns a list with components cnt and bin. n(k) counts the number of values in x that lie between edges(k) <= x(i) < edges(k+1). The last counts any values of x that match edges(n). Values outside the values in edges are not counted. Use -Inf and Inf in edges to include all values.

```
bin[i] returns k if edges(k) <= x(i) < edges(k+1), and 0 if x[i] lies outside the grid.
```

histss

Histogram Bin-width Optimization

## **Description**

Method for selecting the bin size of time histograms.

# Usage

```
histss(x, n = 100, plotting = FALSE)
```

hooke\_jeeves 161

# **Arguments**

X	numeric vector or matrix.
n	maximum number of bins.
plotting	logical; shall a histogram be plotted.

#### **Details**

Bin sizes of histograms are optimized in a way to best displays the underlying spike rate, for example in neurophysiological studies.

## Value

Returns the same list as the hist function; the list is invisible if the histogram is plotted.

# References

Shimazaki H. and S. Shinomoto. A method for selecting the bin size of a time histogram. Neural Computation (2007) Vol. 19(6), 1503-1527

#### See Also

```
hist, histc
```

## **Examples**

```
x <- sin(seq(0, pi/2, length.out = 200))
H <- histss(x, n = 50, plotting = FALSE)
## Not run:
plot(H, col = "gainsboro") # Compare with hist(x), or
hist(x, breaks = H$breaks) # the same
## End(Not run)</pre>
```

hooke\_jeeves

Hooke-Jeeves Function Minimization Method

# **Description**

An implementation of the Hooke-Jeeves algorithm for derivative-free optimization.

# Usage

```
hooke_jeeves(x0, fn, ..., lb = NULL, ub = NULL, tol = 1e-08,
maxfeval = 10000, target = Inf, info = FALSE)
```

hooke\_jeeves

## **Arguments**

x0 starting vector.

fn nonlinear function to be minimized.

. . . additional arguments to be passed to the function.

1b, ub lower and upper bounds.

tol relative tolerance, to be used as stopping rule.

maxfeval maximum number of allowed function evaluations.

target iteration stops when this value is reached.

info logical, whether to print information during the main loop.

#### **Details**

This method computes a new point using the values of f at suitable points along the orthogonal coordinate directions around the last point.

#### Value

List with following components:

xmin minimum solution found so far.

fmin value of f at minimum.

count number of function evaluations.

convergence NOT USED at the moment.

info special info from the solver.

# Note

Hooke-Jeeves is notorious for its number of function calls. Memoization is often suggested as a remedy.

For a similar implementation of Hooke-Jeeves see the 'dfoptim' package.

Horner's Rule

# **Description**

Compute the value of a polynomial via Horner's Rule.

## Usage

```
horner(p, x)
hornerdefl(p, x)
```

horner

## Arguments

- p Numeric vector representing a polynomial.
- x Numeric scalar, vector or matrix at which to evaluate the polynomial.

### **Details**

horner utilizes the Horner scheme to evaluate the polynomial and its first derivative at the same time.

The polynomial  $p = p_1 * x^n + p_2 * x^{n-1} + ... + p_n * x + p_{n+1}$  is hereby represented by the vector  $p_1, p_2, ..., p_n, p_{n+1}$ , i.e. from highest to lowest coefficient.

hornerdef1 uses a similar approach to return the value of p at x and a polynomial q that satisfies

$$p(t) = q(t) * (t - x) + r, r constant$$

which implies r=0 if x is a root of p. This will allow for a repeated root finding of polynomials.

## Value

horner returns a list with two elements, list(y=...,dy=...) where the first list elements returns the values of the polynomial, the second the values of its derivative at the point(s) x.

hornerdefl returns a list list(y=...,dy=...) where q represents a polynomial, see above.

### Note

For fast evaluation, there is no error checking for p and x, which both must be numerical vectors (x can be a matrix in horner).

householder

Householder Reflections

# Description

Householder reflections and QR decomposition

## Usage

householder(A)

# **Arguments**

Α

numeric matrix with nrow(A)>=ncol(A).

## **Details**

The Householder method applies a succession of elementary unitary matrices to the left of matrix A. These matrices are the so-called Householder reflections.

## Value

List with two matrices Q and R, Q orthonormal and R upper triangular, such that A=Q%\*%R.

# References

```

humps

Matlab Test Functions

## **Description**

Matlab test functions.

# Usage

```
humps(x)
sinc(x)
psinc(x, n)
```

# Arguments

x numeric scalar or vector.

n positive integer.

## **Details**

humps is a test function for finding zeros, for optimization and integration. Its root is at x = 1.2995, a (local) minimum at x = 0.6370, and the integral from 0.5 to 1.0 is 8.0715.

sinc is defined as  $sinc(t) = \frac{\sin(\pi t)}{\pi t}$ . It is the continuous inverse Fourier transform of the rectangular pulse of width  $2\pi$  and height 1.

psinc is the 'periodic sinc function' and is defined as  $psinc(x, n) = \frac{\sin(xn/2)}{n\sin(x/2)}$ .

# Value

Numeric scalar or vector.

```
## Not run:
plot(humps(), type="l"); grid()

x <- seq(0, 10, length=101)
plot(x, sinc(x), type="l"); grid()
## End(Not run)</pre>
```

hurstexp 167

hurstexp	Hurst Exponent	

# Description

Calculates the Hurst exponent using R/S analysis.

### Usage

```
hurstexp(x, d = 50, display = TRUE)
```

## **Arguments**

x a time series.

d smallest box size; default 50.

display logical; shall the results be printed to the console?

#### **Details**

hurstexp(x) calculates the Hurst exponent of a time series x using R/S analysis, after Hurst, with slightly different approaches, or corrects it with small sample bias, see for example Weron.

These approaches are a corrected R/S method, an empirical and corrected empirical method, and a try at a theoretical Hurst exponent. It should be mentioned that the results are sometimes very different, so providing error estimates will be highly questionable.

Optimal sample sizes are automatically computed with a length that possesses the most divisors among series shorter than x by no more than 1 percent.

## Value

hurstexp(x) returns a list with the following components:

- Hs simplified R over S approach
- Hrs corrected R over S Hurst exponent
- He empirical Hurst exponent
- Hal corrected empirical Hurst exponent
- Ht theoretical Hurst exponent

# Note

Derived from Matlab code of R. Weron, published on Matlab Central.

hypot

Hypotenuse Function

# **Description**

Square root of sum of squares

# Usage

```
hypot(x, y)
```

## **Arguments**

х, у

Vectors of real or complex numbers of the same size

# **Details**

Element-by-element computation of the square root of the sum of squares of vectors resp. matrices x and y.

## Value

Returns a vector or matrix of the same size.

### Note

Returns c() if x or y is empty and the other one has length 1. If one input is scalar, the other a vector, the scalar will be extended to a vector of appropriate length. In all other cases, x and y have to be of the same size.

```
hypot(3,4)
hypot(1, c(3, 4, 5))
hypot(c(0, 0), c(3, 4))
```

170 ifft

ifft

Inverse Fast Fourier Transformation

# Description

Performs the inverse Fast Fourier Transform.

# Usage

```
ifft(x)
ifftshift(x)
fftshift(x)
```

# **Arguments**

Х

a real or complex vector

# **Details**

ifft returns the value of the normalized discrete, univariate, inverse Fast Fourier Transform of the values in x.

ifftshift and fftshift shift the zero-component to the center of the spectrum, that is swap the left and right half of x.

### Value

Real or complex vector of the same length.

# Note

Almost an alias for R's fft(x, inverse=TRUE), but dividing by length(x).

# See Also

fft

```
x <- c(1, 2, 3, 4)
(y <- fft(x))
ifft(x)
ifft(y)

inpolygon

Polygon Region

### **Description**

Points inside polygon region.

## Usage

```
inpolygon(x, y, xp, yp, boundary = FALSE)
```

### **Arguments**

x, y x-, y-coordinates of points to be tested for being inside the polygon region.

xp, yp coordinates of the vertices specifying the polygon. boundary Logical; does the boundary belong to the interior.

## **Details**

For a polygon defined by points (xp,yp), determine if the points (x,y) are inside or outside the polygon. The boundary can be included or excluded (default) for the interior.

#### Value

Logical vector, the same length as x.

## Note

Special care taken for points on the boundary.

integral

Adaptive Numerical Integration

## **Description**

Combines several approaches to adaptive numerical integration of functions of one variable.

# Usage

## **Arguments**

fun integrand, univariate (vectorized) function.

xmin, xmax endpoints of the integration interval.

method integration procedure, see below.

no\_intervals number of subdivisions at at start.

random logical; shall the length of subdivisions be random.

reltol relative tolerance.

abstol absolute tolerance; not used.

... additional parameters to be passed to the function.

#### **Details**

integral combines the following methods for adaptive numerical integration (also available as separate functions):

- Kronrod (Gauss-Kronrod)
- Clenshaw (Clenshaw-Curtis; not yet made adaptive)
- Simpson (adaptive Simpson)

Recommended default method is Gauss-Kronrod. Also try Clenshaw-Curtis that may be faster at times.

Most methods require that function f is vectorized. This will be checked and the function vectorized if necessary.

By default, the integration domain is subdivided into no\_intervals subdomains to avoid 0 results if the support of the integrand function is small compared to the whole domain. If random is true, nodes will be picked randomly, otherwise forming a regular division.

If the interval is infinite, quadinf will be called that accepts the same methods as well. [If the function is array-valued, quadv is called that applies an adaptive Simpson procedure, other methods are ignored – not true anymore.]

# Value

Returns the integral, no error terms given.

# Note

integral does not provide 'new' functionality, everything is already contained in the functions called here. Other interesting alternatives are Gauss-Richardson (quadgr) and Romberg (romberg) integration.

integral2

Numerically Evaluate Double and Triple Integrals

# **Description**

Numerically evaluate a double integral, resp. a triple integral by reducing it to a double integral.

## Usage

### Arguments

fun	function
xmin, xmax	lower and upper limits of x.
ymin, ymax	lower and upper limits of y.
zmin, zmax	lower and upper limits of z.
sector	logical.
reltol	relative tolerance.
abstol	absolute tolerance.
maxlist	maximum length of the list of rectangles.
singular	logical; are there singularities at vertices.
vectorized	logical; is the function fully vectorized.
	additional parameters to be passed to the function.

#### **Details**

integral 2 implements the 'TwoD' algorithm, that is Gauss-Kronrod with (3, 7)-nodes on 2D rectangles.

The borders of the domain of integration must be finite. The limits of y, that is ymin and ymax, can be constants or scalar functions of x that describe the lower and upper boundaries. These functions must be vectorized.

integral 2 attempts to satisfy ERRBND  $\leftarrow$  max(AbsTo1,RelTo1\*|Q|). This is absolute error control when |Q| is sufficiently small and relative error control when |Q| is larger.

The function fun itself must be fully vectorized: It must accept arrays X and Y and return an array Z = f(X,Y) of corresponding values. If option vectorized is set to FALSE the procedure will enforce this vectorized behavior.

With sector=TRUE the region is a generalized sector that is described in polar coordinates (r,theta) by

```
\emptyset <= a <= theta <= b - a and b must be constants c <= r <= d - c and d can be constants or ...
```

... functions of theta that describe the lower and upper boundaries. Functions must be vectorized. NOTE Polar coordinates are used only to describe the region – the integrand is f(x,y) for both kinds of regions.

integral2 can be applied to functions that are singular on a boundary. With value singular=TRUE, this option causes integral2 to use transformations to weaken singularities for better performance.

integral 3 also accepts functions for the inner interval limits. ymin, ymax must be constants or functions of one variable (x), zmin, zmax constants or functions of two variables (x, y), all functions vectorized.

The triple integral will be first integrated over the second and third variable with integral2, and then integrated over a single variable with integral.

#### Value

Returns a list with Q the integral and error the error term.

#### Note

To avoid recursion, a possibly large matrix will be used and passed between subprograms. A more efficient implementation may be possible.

interp1

One-dimensional Interpolation

# **Description**

One-dimensional interpolation of points.

# Usage

#### **Arguments**

x Numeric vector; points on the x-axis; at least two points require; will be sorted if necessary.

interp1

У	Numeric vector; values of the assumed underlying function; x and y must be of the same length.
xi	Numeric vector; points at which to compute the interpolation; all points must lie between $min(x)$ and $max(x)$ .
method	One of "constant", "linear", "nearest", "spline", or "cubic"; default is "linear"

## **Details**

Interpolation to find yi, the values of the underlying function at the points in the vector xi.

Methods can be:

linear	linear interpolation (default)
constant	constant between points
nearest	nearest neighbor interpolation
spline	cubic spline interpolation
cubic	cubic Hermite interpolation

## Value

Numeric vector representing values at points xi.

### Note

Method 'spline' uses the spline approach by Moler et al., and is identical with the Matlab option of the same name, but slightly different from R's spline function.

The Matlab option "cubic" seems to have no direct correspondence in R. Therefore, we simply use pchip here.

## See Also

```
approx, spline
```

```
x <- c(0.8, 0.3, 0.1, 0.6, 0.9, 0.5, 0.2, 0.0, 0.7, 1.0, 0.4)
y <- x^2
xi <- seq(0, 1, len = 81)
yl <- interp1(x, y, xi, method = "linear")
yn <- interp1(x, y, xi, method = "nearest")
ys <- interp1(x, y, xi, method = "spline")

## Not run:
plot(x, y); grid()
lines(xi, yl, col="blue", lwd = 2)
lines(xi, yn, col="black", lty = 2)
lines(xi, ys, col="red")

## End(Not run)</pre>
```

interp2 179

interp2

Two-dimensional Data Interpolation

# **Description**

Two-dimensional data interpolation similar to a table look-up.

## Usage

```
interp2(x, y, Z, xp, yp, method = c("linear", "nearest", "constant"))
```

## **Arguments**

x, y	vectors with monotonically increasing elements, representing x- and y-coordinates of the data values in Z.
Z	numeric length(y)-by-length(x) matrix.
xp, yp	x-, y-coordinates of points at which interpolated values will be computed.
method	interpolation method, "linear" the most useful.

#### **Details**

Computes a vector containing elements corresponding to the elements of xp and yp, determining by interpolation within the two-dimensional function specified by vectors x and y, and matrix Z.

x and y must be monotonically increasing. They specify the points at which the data Z is given. Therefore, length(x) = nrow(Z) and length(y) = ncol(Z) must be satisfied.

xp and yp must be of the same length.

The functions appears vectorized as xp, yp can be vectors, but internally they are treated in a for loop.

inv

# Value

Vector the length of xp of interpolated values.

For methods "constant" and "nearest" the intervals are considered closed from left and below. Out of range values are returned as NAs.

## Note

The corresponding Matlab function has also the methods "cubic" and "spline". If in need of a nonlinear interpolation, take a look at barylag2d in this package and the example therein.

# See Also

```
interp1, barylag2d
```

# **Examples**

```
## Not run:
    x <- linspace(-1, 1, 11)
    y <- linspace(-1, 1, 11)
    mgrid <- meshgrid(x, y)
    Z <- mgrid$X^2 + mgrid$Y^2
    xp <- yp <- linspace(-1, 1, 101)

method <- "linear"
    zp <- interp2(x, y, Z, xp, yp, method)
    plot(xp, zp, type = "1", col = "blue")

method = "nearest"
    zp <- interp2(x, y, Z, xp, yp, method)
    lines(xp, zp, col = "red")
    grid()

## End(Not run)</pre>
```

inv

Matrix Inverse (Matlab Style)

## **Description**

Invert a numeric or complex matrix.

# Usage

```
inv(a)
```

# **Arguments**

а

real or complex square matrix

invlap 181

## **Details**

Computes the matrix inverse by calling solve(a) and catching the error if the matrix is nearly singular.

### Value

square matrix that is the inverse of a.

#### Note

inv() is the function name used in Matlab/Octave.

### See Also

solve

# **Examples**

```
A <- hilb(6)
B <- inv(A)
B
# Compute the inverse matrix through Cramer's rule:
n <- nrow(A)
detA <- det(A)
b <- matrix(NA, nrow = n, ncol = n)
for (i in 1:n) {
    for (j in 1:n) {
        b[i, j] <- (-1)^(i+j) * det(A[-j, -i]) / detA
    }
}</pre>
```

invlap

Inverse Laplacian

# Description

Numerical inversion of Laplace transforms.

# Usage

```
invlap(Fs, t1, t2, nnt, a = 6, ns = 20, nd = 19)
```

## **Arguments**

Fs	function representing the function to be inverse-transformed.
t1, t2	end points of the interval.
nnt	number of grid points between t1 and t2.
а	shift parameter; it is recommended to preserve value 6.
ns, nd	further parameters, increasing them leads to lower error.

182 invlap

#### **Details**

The transform Fs may be any reasonable function of a variable s^a, where a is a real exponent. Thus, the function invlap can solve fractional problems and invert functions Fs containing (ir)rational or transcendental expressions.

#### Value

Returns a list with components x the x-coordinates and y the y-coordinates representing the original function in the interval [t1, t2].

#### Note

Based on a presentation in the first reference. The function invlap on MatlabCentral (by) served as guide. The Talbot procedure from the second reference could be an interesting alternative.

## End(Not run)
```

isempty

isempty Property

# Description

Determine if an object is empty.

# Usage

```
isempty(x)
```

# Arguments

x

an R object

# **Details**

An empty object has length zero.

### Value

TRUE if x has length 0; otherwise, FALSE.

```
\label{eq:sempty} \begin{array}{ll} isempty(c(0)) & \# \ FALSE \\ isempty(matrix(0,\ 1,\ 0)) \ \# \ TRUE \end{array}
```

184 isposdef

isposdef

Positive Definiteness

# Description

Test for positive definiteness.

# Usage

```
isposdef(A, psd = FALSE, tol = 1e-10)
```

# Arguments

A symmetric matrix

psd logical, shall semi-positive definiteness be tested?

tol tolerance to check symmetry and Cholesky decomposition.

### **Details**

Whether matrix A is positive definite will be determined by applying the Cholesky decomposition. The matrix must be symmetric.

With psd=TRUE the matrix will be tested for being semi-positive definite. If not positive definite, still a warning will be generated.

### Value

Returns TRUE or FALSE.

```
A <- magic(5)
# isposdef(A)
## [1] FALSE
## Warning message:
## In isposdef(A) : Matrix 'A' is not symmetric.
## FALSE

A <- t(A) %*% A
isposdef(A)
## [1] TRUE

A[5, 5] <- 0
isposdef(A)
## [1] FALSE</pre>
```

isprime 185

isprime

isprime Property

# Description

Vectorized version, returning for a vector or matrix of positive integers a vector of the same size containing 1 for the elements that are prime and 0 otherwise.

## Usage

```
isprime(x)
```

### **Arguments**

Х

vector or matrix of nonnegative integers

### **Details**

Given an array of positive integers returns an array of the same size of 0 and 1, where the i indicates a prime number in the same position.

### Value

array of elements 0, 1 with 1 indicating prime numbers

# See Also

factors, primes

```
x <- matrix(1:10, nrow=10, ncol=10, byrow=TRUE)
x * isprime(x)

# Find first prime number octett:
octett <- c(0, 2, 6, 8, 30, 32, 36, 38) - 19
while (TRUE) {
    octett <- octett + 210
    if (all(as.logical(isprime(octett)))) {
        cat(octett, "\n", sep=" ")
        break
    }
}</pre>
```

186 itersolve

|--|--|

## **Description**

Iterative solutions of systems of linear equations.

# Usage

```
itersolve(A, b, x0 = NULL, nmax = 1000, tol = .Machine$double.eps^(0.5), method = c("Gauss-Seidel", "Jacobi", "Richardson"))
```

### **Arguments**

A numerical matrix, square and non-singular.

b numerical vector or column vector.

x0 starting solution for iteration; defaults to null vector.

nmax maximum number of iterations.

tol relative tolerance.

method iterative method, Gauss-Seidel, Jacobi, or Richardson.

### **Details**

Iterative methods are based on splitting the matrix A=(P-A)-A with a so-called 'preconditioner' matrix P. The methods differ in how to choose this preconditioner.

## Value

Returns a list with components x the solution, iter the number of iterations, and method the name of the method applied.

#### Note

Richardson's method allows to specify a 'preconditioner'; this has not been implemented yet.

```

jacobian

Jacobian Matrix

# Description

Jacobian matrix of a function  $R^n -> R^m$ .

## Usage

```
jacobian(f, x0, heps = .Machine$double.eps^(1/3), ...)
```

## **Arguments**

```
f m functions of n variables.

x0 Numeric vector of length n.

heps This is h in the derivative formula.

parameters to be passed to f.
```

#### **Details**

Computes the derivative of each funktion  $f_j$  by variable  $x_i$  separately, taking the discrete step h.

### Value

Numeric m-by-n matrix J where the entry J[j,i] is  $\frac{\partial f_j}{\partial x_i}$ , i.e. the derivatives of function  $f_j$  line up in row i for  $x_1,\ldots,x_n$ .

### Note

Obviously, this function is not vectorized.

188 kriging

### See Also

gradient

### **Examples**

kriging

*Interpolation by Kriging* 

### **Description**

Simple and ordinary Kriging interpolation and interpolating function.

## Usage

```
kriging(u, v, u0, type = c("ordinary", "simple"))
```

## **Arguments**

u an nxm-matrix of n points in the m-dimensional space.
 v an n-dim. (column) vector of interpolation values.
 u0 a kxm-matrix of k points in R^m to be interpolated.
 type character; values 'simple' or 'ordinary'; no partial matching.

### **Details**

Kriging is a geo-spatial estimation procedure that estimates points based on the variations of known points in a non-regular grid. It is especially suited for surfaces.

### Value

kriging returns a k-dim. vektor of interpolation values.

### Note

In the literature, different versions and extensions are discussed.

190 L1linreg

### **Description**

Kronecker tensor product of two matrices.

## Usage

```
kron(a, b)
```

## **Arguments**

a real or complex matrixb real or complex matrix

## **Details**

The Kronecker product is a large matrix formed by all products between the elements of a and those of b. The first left block is a11\*b, etc.

### Value

```
an (n*p \times m*q-matrix, if a is (n \times m and b is (p \times q)).
```

#### Note

kron() is an alias for the R function kronecker(), which can also be executed with the binary operator '%x%'.

# **Examples**

```
a <- diag(1, 2, 2)
b <- matrix(1:4, 2, 2)
kron(a, b)
kron(b, a)</pre>
```

L1linreg

L1 Linear Regression

# **Description**

Solve the linear system A x = b in an Lp sense, that is minimize the term sum  $|b - A x|^p$ . The case p=1 is also called "least absolute deviation" (LAD) regression.

## Usage

```
L1linreg(A, b, p = 1, tol = 1e-07, maxiter = 200)
```

L1linreg 191

## **Arguments**

A	matrix of independent variables.
b	independent variables.
p	the p in L $^p$ norm, p<=1.
tol	relative tolerance.
maxiter	maximum number of iterations.

#### **Details**

L1/Lp regression is here solved applying the "iteratively reweighted least square" (IRLS) method in which each step involves a weighted least squares problem.

If an intercept term is required, add a unit column to A.

#### Value

Returns a list with components x the linear coefficients describing the solution, reltol the relative tolerance reached, and niter the number of iterations.

#### Note

In this case of p=1, the problem would be better approached by use of linear programming methods.

Laguerre's Method

# Description

Laguerre's method for finding roots of complex polynomials.

## Usage

```
laguerre(p, x0, nmax = 25, tol = .Machine\$double.eps^(1/2))
```

## **Arguments**

p real or complex vector representing a polynomial.

x0 real or complex point near the root.

nmax maximum number of iterations.

tol absolute tolerance.

# **Details**

Uses values of the polynomial and its first and second derivative.

## Value

The root found, or a warning about the number of iterations.

### Note

Computations are caried out in complex arithmetic, and it is possible to obtain a complex root even if the starting estimate is real.

### **Examples**

```
# 1 x^5 - 5.4 x^4 + 14.45 x^3 - 32.292 x^2 + 47.25 x - 26.46

p <- c(1.0, -5.4, 14.45, -32.292, 47.25, -26.46)

laguerre(p, 1) #=> 1.2

laguerre(p, 2) #=> 2.099987 (should be 2.1)

laguerre(p, 2i) #=> 0+2.236068i (+- 2.2361i, i.e sqrt(-5))
```

lambertWp

Lambert's W Function

## **Description**

Principal real branch of the Lambert W function.

## Usage

```
lambertWp(x)
lambertWn(x)
```

### **Arguments**

Х

Numeric vector of real numbers  $\geq = -1/e$ .

#### **Details**

The Lambert W function is the inverse of x --> x e<sup>x</sup>, with two real branches, W0 for x >= -1/e and W-1 for  $-1/e \le x \le 0$ . Here the principal branch is called lambertWp, tho other one lambertWp, computed for real x.

The value is calculated using an iteration that stems from applying Halley's method. This iteration is quite fast and accurate.

The functions is not really vectorized, but at least returns a vector of values when presented with a numeric vector of length >= 2.

#### Value

Returns the solution w of  $w \neq \exp(w) = x$  for real x with NaN if  $x < 1/\exp(1)$  (resp. x >= 0 for the second branch).

#### Note

See the examples how values for the second branch or the complex Lambert W function could be calculated by Newton's method.

laplacian 195

## **Description**

Numerically compute the Laplacian of a function.

## Usage

```
laplacian(f, x0, h = .Machine$double.eps^(1/4), ...)
```

## **Arguments**

```
f univariate function of several variables.
```

x0 point in  $\mathbb{R}^n$ .

h step size.

... variables to be passed to f.

## **Details**

Computes the Laplacian operator  $f_{x_1x_1} + \ldots + f_{x_nx_n}$  based on the three-point central difference formula, expanded to this special case.

Assumes that the function has continuous partial derivatives.

# Value

Real number.

Lebesgue Constant

# Description

Estimates the Lebesgue constant.

## Usage

```
lebesgue(x, refine = 4, plotting = FALSE)
```

### **Arguments**

x numeric vector of grid points

refine refine the grid with 2^refine grid points; can only be an integer between 2 and

10, default 4.

plotting shall the Lebesgue function be plotted.

### **Details**

The Lebesgue constant gives an estimation  $||P_n f|| \le L||f||$  (in minimax norm) where  $P_n f$  is the interpolating polynomial of order n for f on an interval [a, b].

## Value

Lebesgue constant for the given grid points.

### Note

The Lebesgue constant plays an important role when estimating the distance of interpolating polynomials from the minimax solution (see the Remez algorithm).

legendre 197

legendre

Legendre Functions (Matlab Style)

### **Description**

Calculate the values of (associated) Legendre functions.

### Usage

```
legendre(n, x)
```

# **Arguments**

- n degree of the Legendre polynomial involved.
- x real points to evaluate Legendre's functions at.

#### **Details**

legendre(n, x) computes the associated Legendre functions of degree n and order  $m=0,1,\ldots,n$ , evaluated for each element of x where x must contain real values in [-1,1].

If x is a vector, then L=legendre(n,x) is an (n+1)-by-N matrix, where N=length(x). Each element L[m+1,i] corresponds to the associated Legendre function of degree legendre(n,x) and order m evaluated at x[i].

Note that the first row of L is the Legendre polynomial evaluated at x.

## Value

Returns a matrix of size (n+1)-by-N where N=length(x).

#### Note

Legendre functions are solutions to Legendre's differential equation (it occurs when solving Laplace's equation in spherical coordinates).

```

linearproj, affineproj

Linear Projection onto a Subspace

### **Description**

Computes the projection of points in the columns of B onto the linear subspace spaned by the columns of A, resp. the projection of a point onto an affine subspace and its distance.

## Usage

```
linearproj(A, B)
affineproj(x0, C, b, unbound = TRUE, maxniter = 100)
```

### **Arguments**

A	Matrix whose columns span a subspace of some R^n.
В	Matrix whose columns are to be projected.
x0	Point in R^n to be projected onto $C x = b$ .
C, b	Matrix and vector, defining an affine subspace as $C x = b$
unbound	Logical; require all $x \ge 0$ if unbound is false.
maxniter	Maximum number of iterations (if is unbound is false).

#### **Details**

linearproj projects points onto a *linear* subspace in R^n. The columns of A are assumed be the basis of a linear subspace, esp. they are required to be linearly independent. The columns of matrix B define points in R^n that will be projected onto A, and their resp. coefficients in terms of the basis in A are computed.

The columns of A need to be linearly independent; if not, generate an orthonormal basis of this subspace with orth(A). If you want to project points onto a subspace that is defined by  $A \times A = \emptyset$ , then generate an orthonormal basis of the nullspace of A with null(A).

linearproj, affineproj 199

Technically, the orthogonal projection can be determined by a finite 'Fourier expansion' with coefficients calculated as scalar products, see the examples.

affineproj projects (single) points onto an affine subspace defined by  $A \times B$  and calculates the distance of  $\times B$  from this subspace. The calculation is based on the following formula:

$$p = (I - A'(AA')^{-1})x0 + A'(AA')^{-1}b$$

Technically, if a is one solution of  $C \times B$ , then the projection onto C can be derived from the projection onto  $S = C \times B$  with  $proj_C(x) = a + proj_S(x - a)$ , see the examples.

In case the user requests the coordinates of the projected point to be positive, an iteration procedure is started where negative coordinates are set to zero in each iteration.

#### Value

The functions linearproj returns a list with components P and Q. The columns of P contain the coefficients – in the basis of A – of the corresponding projected points in B, and the columns of Q are the the coordinates of these points in the natural coordinate system of  $R^n$ .

affineproj returns a list with components proj, dist, and niter. proj is the projected point, dist the distance from the subspace (and niter the number of iterations if positivity of the coordinates was requested.).

#### Note

Some timings show that these implementations are to a certain extent competitive with direct applications of quadprog.

line\_integral

*Line integral (in the complex plane)* 

## Description

Provides complex line integrals.

### Usage

```
line_integral(fun, waypoints, method = NULL, reltol = 1e-8, ...)
```

### **Arguments**

fun integrand, complex (vectorized) function.

method integration procedure, see below.

waypoints complex integration: points on the integration curve.

reltol relative tolerance.

... additional parameters to be passed to the function.

#### **Details**

line\_integral realizes complex line integration, in this case straight lines between the waypoints. By passing discrete points densely along the curve, arbitrary line integrals can be approximated.

line\_integral will accept the same methods as integral; default is integrate from Base R.

## Value

Returns the integral, no error terms given.

```

linprog

Linear Programming Solver

# Description

Solves simple linear programming problems, allowing for inequality and equality constraints as well as lower and upper bounds.

## Usage

#### **Arguments**

СС	defines the linear objective function.
A	matrix representing the inequality constraints $A \times = b$ .
b	vector, right hand side of the inequalities.
Aeq	matrix representing the equality constraints Aeq $x \le eq$ .
beq	vector, right hand side of the inequalities.
lb	lower bounds, if not NULL must all be greater or equal 0.
ub	upper bounds, if not NULL must all be greater or equal 1b.
x0	feasible base vector, will not be used at the moment.
10	index set of x0, will not be used at the moment.
bigM	big-M constant, will be used for finding a base vector.
maxiter	maximum number of iterations.
maximize	logical; shall the objective be minimized or maximized?

linprog 203

## **Details**

Solves linear programming problems of the form mincc' \* x such that

$$A * x \le b$$
$$A_{eq} * x = b_{eq}$$
$$lb \le x \le ub$$

#### Value

List with

- x the solution vector.
- fval the value at the optimal solution.
- errno, mesage the error number and message.

#### Note

This is a first version that will be unstable at times. For real linear programming problems use package lpSolve.

linspace

Linearly Spaced Sequences

# Description

Generate linearly spaced sequences.

# Usage

```
linspace(x1, x2, n = 100)
```

# Arguments

x1	numeric scalar specifying starting point
x2	numeric scalar specifying ending point
n	numeric scalar specifying number of points to be generated

### **Details**

These functions will generate n linearly spaced points between x1 and x2.

If n < 2, the result will be the ending point x2.

## Value

vector containing n points between x1 and x2 inclusive.

## See Also

```
logspace, seq
```

```
linspace(1, 10, 9)
```

Log-linearly Spaced Sequences

# Description

Generate log-linearly spaced sequences.

# Usage

```
logspace(x1, x2, n = 50)
logseq(x1, x2, n = 100)
```

# Arguments

x1	numeric scalar specifying starting point
x2	numeric scalar specifying ending point
n	numeric scalar specifying number of points to be generated

### **Details**

These functions will generate logarithmically resp. exponentially spaced points between x1 and x2 resp.  $10^x1$  and  $10^x2$ .

If n < 2, the result will be the ending point x2. For logspace(), if x2 = pi, the endpoint will be pi and not 10 $^$ pi!

# Value

vector containing n points between x1 and x2 inclusive.

# See Also

```
logspace, seq
```

```
logspace(1, pi, 36)
logseq(0.05, 1, 20)
```

lsqlin 207

Linear Least-Squares Fitting

## Description

Solves linearly constrained linear least-squares problems.

## Usage

```
lsqlin(A, b, C, d, tol = 1e-13)
```

### **Arguments**

Α	nxm-matrix defining the least-squares problem.
b	vector or colum matrix with n rows; when it has more than one column it describes several least-squares problems.
С	pxm-matrix for the constraint system.
d	vector or px1-matrix, right hand side for the constraints.
tol	tolerance to be passed to pinv.

## **Details**

lsqlin(A,b,C,d) minimizes | | A\*x -b | | (i.e., in the least-squares sense) subject to C\*x = d.

### Value

Returns a least-squares solution as column vector, or a matrix of solutions in the columns if b is a matrix with several columns.

# Note

The Matlab function lsqlin solves a more general problem, allowing additional linear inequalities and bound constraints. In pracma this task is solved applying function lsqlincon.

Linear Least-Squares Fitting with linear constraints

### **Description**

Solves linearly constrained linear least-squares problems.

## Usage

## Arguments

С	mxn-matrix defining the least-squares problem.
d	vector or a one colum matrix with m rows
A	pxn-matrix for the linear inequality constraints.
b	vector or px1-matrix, right hand side for the constraints.
Aeq	qxn-matrix for the linear equality constraints.
beq	vector or qx1-matrix, right hand side for the constraints.
1b	lower bounds, a scalar will be extended to length n.
ub	upper bounds, a scalar will be extended to length n.

#### **Details**

lsqlincon(C,d,A,b,Aeq,beq,lb,ub) minimizes ||C\*x-d|| (i.e., in the least-squares sense) subject to the following constraints:  $A*x \le b$ , Aeq\*x = beq, and  $1b \le x \le ub$ .

It applies the quadratic solver in quadprog with an active-set method for solving quadratic programming problems.

If some constraints are NULL (the default), they will not be taken into account. In case no constraints are given at all, it simply uses qr.solve.

### Value

Returns the least-squares solution as a vector.

#### Note

Function 1sqlin in pracma solves this for equality constraints only, by computing a base for the nullspace of Aeq. But for linear inequality constraints there is no simple linear algebra 'trick', thus a real optimization solver is needed.

lsqnonlin

Nonlinear Least-Squares Fitting

#### **Description**

1sqnonlin solves nonlinear least-squares problems, including nonlinear data-fitting problems, through the Levenberg-Marquardt approach.

1sqnonneg solve nonnegative least-squares constraints problem.

## Usage

```
lsqnonlin(fun, x0, options = list(), ...)
lsqnonneg(C, d)

lsqsep(flist, p0, xdata, ydata, const = TRUE)
lsqcurvefit(fun, p0, xdata, ydata)
```

### **Arguments**

fun User-defined, vector-valued function.

x0 starting point.

. . . additional parameters passed to the function.

options list of options, for details see below.

C, d matrix and vector such that  $C \times -d$  will be minimized with  $x \ge 0$ . flist list of (nonlinear) functions, depending on one extra parameter.

p0 starting parameters. xdata, ydata data points to be fitted.

const logical; shall a constant term be included.

#### **Details**

Isopronlin computes the sum-of-squares of the vector-valued function fun, that is if  $f(x) = (f_1(x), \ldots, f_n(x))$  then

$$min||f(x)||_2^2 = min(f_1(x)^2 + \ldots + f_n(x)^2)$$

will be minimized.

x=1 sqnonlin(fun, x0) starts at point x0 and finds a minimum of the sum of squares of the functions described in fun. fun shall return a vector of values and not the sum of squares of the values. (The algorithm implicitly sums and squares fun(x).)

options is a list with the following components and defaults:

- tau: used as starting value for Marquardt parameter.
- tolx: stopping parameter for step length.
- tolg: stopping parameter for gradient.
- maxeval the maximum number of function evaluations.

Typical values for tau are from 1e-6...1e-3...1 with small values for good starting points and larger values for not so good or known bad starting points.

1sqnonneg solves the linear least-squares problem  $C \times -d$ ,  $\times$  nonnegative, treating it through an active-set approach..

1sqsep solves the separable least-squares fitting problem

$$y = a0 + a1*f1(b1,x) + ... + an*fn(bn,x)$$

where fi are nonlinear functions each depending on a single extra paramater bi, and ai are additional linear parameters that can be separated out to solve a nonlinear problem in the bi alone.

lsqcurvefit is simply an application of lsqnonlin to fitting data points. fun(p,x) must be a function of two groups of variables such that p will be varied to minimize the least squares sum, see the example below.

#### Value

1sqnonlin returns a list with the following elements:

- x: the point with least sum of squares value.
- ssq: the sum of squares.
- ng: norm of last gradient.
- nh: norm of last step used.
- mu: damping parameter of Levenberg-Marquardt.
- neval: number of function evaluations.
- errno: error number, corresponds to error message.
- errmess: error message, i.e. reason for stopping.

1sqnonneg returns a list of x the non-negative solition, and resid.norm the norm of the residual.

1sqsep will return the coefficients sparately, a0 for the constant term (being 0 if const=FALSE) and the vectors a and b for the linear and nonlinear terms, respectively.

#### Note

The refined approach, Fletcher's version of the Levenberg-Marquardt algorithm, may be added at a later time; see the references.

lu

LU Matrix Factorization

# Description

LU decomposition of a positive definite matrix as Gaussian factorization.

# Usage

```
lu(A, scheme = c("kji", "jki", "ijk"))
lu_crout(A)
lufact(A)
lusys(A, b)
```

# Arguments

A square positive definite numeric matrix (will not be checked).

scheme order of row and column operations.

b right hand side of a linear system of equations.

lu 215

#### **Details**

For a given matrix A, the LU decomposition exists and is unique iff its principal submatrices of order i=1,...,n-1 are nonsingular. The procedure here is a simple Gauss elimination with or without pivoting.

The scheme abbreviations refer to the order in which the cycles of row- and column-oriented operations are processed. The "ijk" scheme is one of the two compact forms, here the Doolite factorization (the Crout factorization would be similar).

lu\_crout implements the Crout algorithm. For the Doolite algorithm, the L matrix has ones on its diagonal, for the Crout algorithm, the diagonal of the U matrix only has ones.

lufact applies partial pivoting (along the rows). lusys uses LU factorization to solve the linear system A\*x=b.

These function are not meant to process huge matrices or linear systems of equations. Without pivoting they may also be harmed by considerable inaccuracies.

#### Value

lu and lu\_crout return a list with components L and U, the lower and upper triangular matrices such that A=L%\*%U.

lufact returns a list with L and U combined into one matrix LU, the rows used in partial pivoting, and det representing the determinant of A. See the examples how to extract matrices L and U from

lusys returns the solution of the system as a column vector.

#### Note

To get the Crout decomposition of a matrix A do Z < -lu(t(A)); L < -t(Z\$U); U < -t(Z\$L).

magic

Magic Square

# Description

Create a magic square.

### Usage

```
magic(n)
```

## **Arguments**

n

numeric scalar specifying dimensions for the result; n must be a scalar greater than or equal to 3.

### **Details**

A magic square is a square matrix where all row and column sums and also the diagonal sums all have the same value.

This value or the characteristic sum for a magic square of order n is  $sum(1:n^2)/n$ .

### Value

Returns an n-by-n matrix constructed from the integers 1 through N^2 with equal row and column sums.

#### Note

A magic square, scaled by its magic sum, is doubly stochastic.

matlab 217

### Author(s)

P. Roebuck <roebuck@mdanderson.org> for the first R version in the package 'matlab'. The version here is more R-like.

## **Examples**

```
magic(3)
```

matlab

Matlab Compatibility

## Description

Matlab compatibility.

## Usage

```
matlab()
```

### **Details**

Lists all the functions and function names that emulate Matlab functions.

#### Value

Invisible NULL value.

meshgrid

Generate a Mesh Grid

# Description

Generate two matrices for use in three-dimensional plots.

## Usage

```
meshgrid(x, y = x)
```

## Arguments

x numerical vector, represents points along the x-axis.

y numerical vector, represents points along the y-axis.

### **Details**

The rows of the output array X are copies of the vector x; columns of the output array Y are copies of the vector y.

218 mexpfit

#### Value

Returns two matrices as a list with X and Y components.

#### Note

The three-dimensional variant meshgrid(x, y, z) is not yet implemented.

#### See Also

outer

### **Examples**

```
meshgrid(1:5)$X
meshgrid(c(1, 2, 3), c(11, 12))
```

mexpfit

Multi-exponential Fitting

## **Description**

Multi-exponential fitting means fitting of data points by a sum of (decaying) exponential functions, with or without a constant term.

### Usage

```
mexpfit(x, y, p0, w = NULL, const = TRUE, options = list())
```

### **Arguments**

x, y
 p0
 starting values for the exponentials alone; can be positive or negative, but not zero.
 w
 weight vector; not used in this version.
 const
 logical; shall an absolute term be included.

options list of options for lsqnonlin, see there.

#### **Details**

The multi-exponential fitting problem is solved here with with a separable nonlinear least-squares approach. If the following function is to be fitted,

$$y = a_0 + a_1 e^{b_1 x} + \ldots + a_n e^{b_n x}$$

it will be looked at as a nonlinear optimization problem of the coefficients  $b_i$  alone. Given the  $b_i$ , coefficients  $a_i$  are uniquely determined as solution of an (overdetermined) system of linear equations.

mexpfit 219

This approach reduces the dimension of the search space by half and improves numerical stability and accuracy. As a convex problem, the solution is unique and global.

To solve the nonlinear part, the function lsqnonlin that uses the Levenberg-Marquard algorithm will be applied.

#### Value

mexpfit returns a list with the following elements:

- a0: the absolute term, 0 if const is false.
- a: linear coefficients.
- b: coefficient in the exponential functions.
- ssq: the sum of squares for the final fitting.
- iter: number of iterations resp. function calls.
- errmess: an error or info message.

#### Note

As the Jacobian for this expression is known, a more specialized approch would be possible, without using lsqnonlin; see the immoptibox of H. B. Nielsen, Techn. University of Denmark.

mldivide

Matlab backslash operator

### **Description**

Emulate the Matlab backslash operator "\" through QR decomposition.

## Usage

```
mldivide(A, B, pinv = TRUE)
mrdivide(A, B, pinv = TRUE)
```

## Arguments

A, B	Numerical or complex matrices; A and B must have the same number of rows
	(for mldivide) or the same number of columns (for mrdivide)
pinv	logical; shall SVD decomposition be used; default true.

#### **Details**

mldivide performs matrix left division (and mrdivide matrix right division). If A is scalar it performs element-wise division.

If A is square, mldivide is roughly the same as inv(A) %\*% B except it is computed in a different way — using QR decomposition.

If pinv = TRUE, the default, the SVD will be used as pinv(t(A)%\*%A)%\*%t(A)%\*%B to generate results similar to Matlab. Otherwise, qr. solve will be used.

If A is not square,  $x \leftarrow \text{mldivide}(A,b)$  returnes a least-squares solution that minimizes the length of the vector A  $**x \leftarrow b$  (which is equivalent to norm(A  $**x \leftarrow b$ , "F").

#### Value

If A is an n-by-p matrix and B n-by-q, then the result of mldivide(A,B) is a p-by-q matrix (mldivide).

### Note

mldivide(A,B) corresponds to A\B in Matlab notation.

mod, rem

### **Examples**

```
# Solve a system of linear equations
A <- matrix(c(8,1,6, 3,5,7, 4,9,2), nrow = 3, ncol = 3, byrow = TRUE)
b <- c(1, 1, 1)
mldivide(A, b) # 0.066666667 0.06666667

A <- rbind(1:3, 4:6)
mldivide(A, c(1,1)) # -0.5 0 0.5 ,i.e. Matlab/Octave result
mldivide(A, c(1,1), pinv = FALSE) # -1 1 0 R qr.solve result</pre>
```

mod, rem

Integer Division

## Description

Integer division functions and remainders

### Usage

```
mod(n, m)
rem(n, m)
idivide(n, m, rounding = c("fix", "floor", "ceil", "round"))
```

## Arguments

n numeric vector (preferably of integers)

m must be a scalar integer (positive, zero, or negative)

rounding rounding mode.

## **Details**

mod(n,m) is the modulo operator and returns  $n \mod m$ . mod(n,0) is n, and the result always has the same sign as m.

rem(n,m) is the same modulo operator and returns  $n \mod m$ . mod(n,0) is NaN, and the result always has the same sign as n.

idivide(n,m) is integer division, with the same effect as n %/% m or using an optional rounding mode.

### Value

a numeric (integer) value or vector/matrix.

## Note

```
The following relation is fulfilled (for m != 0):

mod(n,m) = n - m * floor(n/m)
```

Mode Mode

### See Also

Binary R operators %/% and %%.

## **Examples**

```
mod(c(-5:5), 5)
rem(c(-5:5), 5)

idivide(c(-2, 2), 3, "fix") # 0 0
idivide(c(-2, 2), 3, "floor") # -1 0
idivide(c(-2, 2), 3, "ceil") # 0 1
idivide(c(-2, 2), 3, "round") # -1 1
```

Mode

*Mode function (Matlab style)* 

### **Description**

Most frequent value in vector or matrix

## Usage

Mode(x)

## **Arguments**

Х

Real or complex vector or of factor levels.

### **Details**

Computes the 'sample mode', i.e. the most frequently occurring value in x.

Among values occurring equally frequently, Mode() chooses the smallest one (for a numeric vector), one with a smallest absolute value (for complex ones) or the first occurring value (for factor levels). A matrix will be changed to a vector.

 $\boldsymbol{\mathcal{E}}$ 

### Value

One element from x and of the same type. The number of occurrences will not be returned.

#### Note

In Matlab/Octave an array dimension can be selected along which to find the mode value; this has not been realized here.

Shadows the R function mode that returns essentially the type of an object.

## See Also

median

## **Examples**

```
x <- round(rnorm(1000), 2)
Mode(x)</pre>
```

moler

Moler Matrix

# Description

Generate the Moler matrix of size  $n \times n$ . The Moler matrix is for testing eigenvalue computations.

# Usage

```
moler(n)
```

# Arguments

n

integer

# **Details**

The Moler matrix for testing eigenvalue computations is a symmetric matrix with exactly one small eigenvalue.

## Value

matrix of size n x n

## See Also

wilkinson

```
(a <- moler(10))
min(eig(a))</pre>
```

224 movavg

movavg

Moving Average Filters

## **Description**

Different types of moving average of a time series.

### Usage

```
movavg(x, n, type=c("s", "t", "w", "m", "e", "r"))
```

### **Arguments**

```
x time series as numeric vector.

n backward window length.

type one of 's', 't', 'w', 'm', 'e', or 'r'; default is 's'.
```

#### **Details**

Types of available moving averages are:

- s for "simple", it computes the simple moving average. n indicates the number of previous data points used with the current data point when calculating the moving average.
- t for "triangular", it computes the triangular moving average by calculating the first simple moving average with window width of ceil(n+1)/2; then it calculates a second simple moving average on the first moving average with the same window size.
- w for "weighted", it calculates the weighted moving average by supplying weights for each element in the moving window. Here the reduction of weights follows a linear trend.
- m for "modified", it calculates the modified moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new value and subtracting the last average from the resulting sum.
- e for "exponential", it computes the exponentially weighted moving average. The exponential moving average is a weighted moving average that reduces influences by applying more weight to recent data points () reduction factor 2/(n+1); or
- r for "running", this is an exponential moving average with a reduction factor of 1/n [same as the modified average?].

#### Value

Vector the same length as time series x.

muller

Muller's Method

#### Description

Muller's root finding method, similar to the secant method, using a parabola through three points for approximating the curve.

226 muller

### Usage

```
muller(f, p0, p1, p2 = NULL, maxiter = 100, tol = 1e-10)
```

### **Arguments**

f function whose root is to be found; function needs to be defined on the complex plain.

p0, p1, p2 three starting points, should enclose the assumed root.

tol relative tolerance, change in successive iterates.

maxiter maximum number of iterations.

### **Details**

Generalizes the secant method by using parabolic interpolation between three points. This technique can be used for any root-finding problem, but is particularly useful for approximating the roots of polynomials, and for finding zeros of analytic functions in the complex plane.

### Value

List of root, fval, niter, and reltol.

#### Note

Muller's method is considered to be (a bit) more robust than Newton's.

#### References

Pseudo- and C code available from the 'Numerical Recipes'; pseudocode in the book 'Numerical Analysis' by Burden and Faires (2011).

nchoosek

**Binomial Coefficients** 

## **Description**

Compute the Binomial coefficients.

# Usage

```
nchoosek(n, k)
```

## **Arguments**

n, k

integers with k between 0 and n

#### **Details**

Alias for the corresponding R function choose.

### Value

```
integer, the Binomial coefficient (\frac{n}{k}).
```

### Note

In Matlab/Octave, if n is a vector all combinations of k elements from vector n will be generated. Here, use the function combs instead.

ndims

Number of Dimensions

## **Description**

Number of matrix or array dimensions.

## Usage

```
ndims(x)
```

## Arguments

Χ

a vector, matrix, array, or list

#### **Details**

Returns the number of dimensions as length(x).

For an empty object its dimension is 0, for vectors it is 1 (deviating from MATLAB), for matrices it is 2, and for arrays it is the number of dimensions, as usual. Lists are considered to be (one-dimensional) vectors.

#### Value

the number of dimensions in a vector, matrix, or array x.

### Note

The result will differ from Matlab when x is a vector.

## See Also

size

```

```

nearest\_spd 229

nearest\_spd

Nearest Symmetric Positive-definite Matrix

## **Description**

Find nearest (in Frobenius norm) symmetric positive-definite matrix to A.

## Usage

```
nearest_spd(A)
```

### **Arguments**

Α

square numeric matrix.

## **Details**

"The nearest symmetric positive semidefinite matrix in the Frobenius norm to an arbitrary real matrix A is shown to be (B + H)/2, where H is the symmetric polar factor of B=(A + A')/2." N. J. Highham

#### Value

Returns a matrix of the same size.

#### References

Nicholas J. Higham (1988). Computing a nearest symmetric positive semidefinite matrix. Linear Algebra and its Applications. Vol. 103, pp.103-118.

230 nelder\_mead

-		
ne	lder	mead

Nelder-Mead Function Minimization Method

## Description

An implementation of the Nelder-Mead algorithm for derivative-free optimization / function minimization.

### Usage

```
nelder_mead(fn, x0, ..., adapt = TRUE,
tol = 1e-08, maxfeval = 5000,
step = rep(1.0, length(x0)))
```

#### Arguments

fn	nonlinear function to be minimized.
x0	starting point for the iteration.
	additional arguments to be passed to the function.
adapt	logical; adapt to parameter dimension.
tol	terminating limit for the variance of function values; can be made *very* small, like tol=1e-50.
maxfeval	maximum number of function evaluations.
step	size and shape of initial simplex; relative magnitudes of its elements should reflect the units of the variables.

#### **Details**

Also called a 'simplex' method for finding the local minimum of a function of several variables. The method is a pattern search that compares function values at the vertices of the simplex. The process generates a sequence of simplices with ever reducing sizes.

The simplex function minimisation procedure due to Nelder and Mead (1965), as implemented by O'Neill (1971), with subsequent comments by Chambers and Ertel 1974, Benyon 1976, and Hill 1978. For another elaborate implementation of Nelder-Mead in R based on Matlab code by Kelley see package 'dfoptim'.

nelder\_mead can be used up to 20 dimensions (then 'tol' and 'maxfeval' need to be increased). With adapt=TRUE it applies adaptive coefficients for the simplicial search, depending on the problem dimension – see Fuchang and Lixing (2012). This approach especially reduces the number of function calls.

nelder\_mead 231

#### Value

List with following components:

xmin minimum solution found.fmin value of f at minimum.

fcount number of iterations performed.

restarts number of restarts.
errmess error message

### Note

Original FORTRAN77 version by R O'Neill; MATLAB version by John Burkardt under LGPL license. Re-implemented in R by Hans W. Borchers.

Neville's Method

## **Description**

Neville's's method of polynomial interpolation.

### Usage

```
neville(x, y, xs)
```

## **Arguments**

x, yx-, y-coordinates of data points defining the polynomial.xssingle point to be interpolated.

### **Details**

Straightforward implementation of Neville's method; not yet vectorized.

### Value

Interpolated value at xs of the polynomial defined by x, y.

#### References

Each textbook on numerical analysis.

### See Also

```
newtonInterp, barylag
```

newmark 233

### **Examples**

```
p <- Poly(c(1, 2, 3))
fp <- function(x) polyval(p, x)

x <- 0:4; y <- fp(x)
xx <- linspace(0, 4, 51)
yy <- numeric(51)
for (i in 1:51) yy[i] <- neville(x, y, xx[i])

## Not run:
ezplot(fp, 0, 4)
points(xx, yy)
## End(Not run)</pre>
```

newmark

Newmark Method

## **Description**

Newmark's is a method to solve higher-order differential equations without passing through the equivalent first-order system. It generalizes the so-called 'leap-frog' method. Here it is restricted to second-order equations.

### Usage

```
newmark(f, t0, t1, y0, ..., N = 100, zeta = 0.25, theta = 0.5)
```

### **Arguments**

f	function in the differential equation $y'' = f(x, y, y')$ ; defined as a function $R \times R^2 \to R$ .
t0, t1	start and end points of the interval.
y0	starting values as row or column vector; $y0$ needs to be a vector of length 2, the first component representing $y(t0)$ , the second $dy/dt(t0)$ .
N	number of steps.
zeta, theta	two non-negative real numbers.
	Additional parameters to be passed to the function.

#### **Details**

Solves second order differential equations using the Newmark method on an equispaced grid of N steps.

Function f must return a vector, whose elements hold the evaluation of f(t,y), of the same dimension as y0. Each row in the solution array Y corresponds to a time returned in t.

The method is 'implicit' unless zeta=theta=0, second order if theta=1/2 and first order accurate if theta!=1/2. theta>=1/2 ensures stability. The condition set theta=1/2; zeta=1/4 (the

234 newtonHorner

defaults) is a popular approach that is unconditionally stable, but introduces oscillatory spurious solutions on long time intervals. (For these simulations it is preferable to use theta>1/2 and zeta> $(theta+1/2)^(1/2)$ .)

No attempt is made to catch any errors in the root finding functions.

#### Value

List with components t for grid (or 'time') points between t0 and t1, and y an n-by-2 matrix with solution variables in columns, i.e. each row contains one time stamp.

#### Note

This is for demonstration purposes only; for real problems or applications please use ode23 or rk4sys.

### **Examples**

newtonHorner

Newton's Root Finding Method for Polynomials.

## **Description**

Finding roots of univariate polynomials.

## Usage

```
newtonHorner(p, x0, maxiter = 50, tol = .Machine$double.eps^0.5)
```

newtonHorner 235

## **Arguments**

p	Numeric vector representing a polynomial.
x0	starting value for newtonHorner().
maxiter	maximum number of iterations; default 100.
tol	absolute tolerance; default eps^(1/2)

### **Details**

Similar to newtonRahson, except that the computation of the derivative is done through the Horner scheme in parallel with computing the value of the polynomial. This makes the algorithm significantly faster.

### Value

Return a list with components root, f.root, the function value at the found root, iter, the number of iterations done, and root, and the estimated precision estim.prec

The estimated precision is given as the difference to the last solution before stop.

newtonRaphson 237

newtonkaphson Kootjinaing inrough Newton-Kaphson or Secant.	newtonRaphson	Rootfinding through Newton-Raphson or Secant.
---	---------------	---

# Description

Finding roots of univariate functions. (Newton never invented or used this method; it should be called more appropriately Simpson's method!)

## Usage

```
newtonRaphson(fun, x0, dfun = NULL, maxiter = 500, tol = 1e-08, ...) newton(fun, x0, dfun = NULL, maxiter = 500, tol = 1e-08, ...)
```

## Arguments

fun	Function or its name as a string.
x0	starting value for newtonRaphson().
dfun	A function to compute the derivative of f. If NULL, a numeric derivative will be computed.
maxiter	maximum number of iterations; default 100.
tol	absolute tolerance; default eps^(1/2)
	Additional arguments to be passed to f.

### **Details**

Well known root finding algorithms for real, univariate, continuous functions.

### Value

Return a list with components root, f.root, the function value at the found root, iter, the number of iterations done, and root, and the estimated precision estim.prec

The estimated precision is given as the difference to the last solution before stop; this may be misleading.

### **Examples**

```
# Legendre polynomial of degree 5 lp5 <- c(63, 0, -70, 0, 15, 0)/8 f <- function(x) polyval(lp5, x) newton(f, 1.0)  # 0.9061798459 correct to 10 decimals in 5 iterations
```

newtonsys

Newton Method for Nonlinear Systems

## **Description**

Newton's method applied to multivariate nonlinear functions.

## Usage

## **Arguments**

Ffun m functions of n variables.

Jfun Function returning a square n-by-n matrix (of partial derivatives) or NULL, the

default.

x0 Numeric vector of length n.maxiter Maximum number of iterations.tol Tolerance, relative accuracy.

... Additional parameters to be passed to f.

#### **Details**

Solves the system of equations applying Newton's method with the univariate derivative replaced by the Jacobian.

### Value

List with components: zero the root found so far, fnorm the square root of sum of squares of the values of f, and iter the number of iterations needed.

### Note

TODO: better error checking, e.g. when the Jacobian is not invertible.

# $fnorm 2.220446e-16
# $niter 8
## Two more problematic examples
F3 <- function(x)
        c(2*x[1] - x[2] - exp(-x[1]), -x[1] + 2*x[2] - exp(-x[2]))
newtonsys(F3, c(0, 0))
# $zero 0.5671433 0.5671433
# $fnorm 0
# $niter 4
## Not run:
F4 <- function(x) # Dennis Schnabel
        c(x[1]^2 + x[2]^2 - 2, exp(x[1] - 1) + x[2]^3 - 2)
newtonsys(F4, c(2.0, 0.5))
# will result in an error ``missing value in ... err<tol && niter<maxiter''</pre>
## End(Not run)
```

nextpow2

Next Power of 2

## **Description**

Smallest power of 2 greater than the argument.

### Usage

```
nextpow2(x)
```

### **Arguments**

Х

numeric scalar, vector, or matrix

240 nnz

## **Details**

Computes the smalest integer n such that  $abs(x) \le 2^n$ . IF x is a vector or matrix, returns the result component-wise. For negative or complex values, the absolute value will be taken.

### Value

```
an integer n such that x \leq 2^n.
```

### See Also

Norm 241

Norm Vector Norm

### **Description**

The Norm function calculates several different types of vector norms for x, depending on the argument p.

#### **Usage**

```
Norm(x, p = 2)
```

## Arguments

Numeric vector; matrices not allowed.Numeric scalar or Inf, -Inf; default is 2

#### **Details**

Norm returns a scalar that gives some measure of the magnitude of the elements of x. It is called the p-norm for values  $-Inf \le p \le Inf$ , defining Hilbert spaces on  $R^n$ .

```
Norm(x) is the Euclidean length of a vecor x; same as Norm(x,2).

Norm(x,p) for finite p is defined as sum(abs(A)^p)^(1/p).

Norm(x,Inf) returns max(abs(x)), while Norm(x,-Inf) returns min(abs(x)).
```

### Value

Numeric scalar (or Inf), or NA if an element of x is NA.

### Note

In Matlab/Octave this is called norm; R's norm function norm(x, "F") ('Frobenius Norm') is the same as Norm(x).

## See Also

norm of a matrix

242 normest

normest

Estimated Matrix Norm

## Description

Estimate the 2-norm of a real (or complex-valued) matrix. 2-norm is also the maximum absolute eigenvalue of M, computed here using the power method.

## Usage

```
normest(M, maxiter = 100, tol = .Machine$double.eps^(1/2))
```

## **Arguments**

M Numeric matrix; vectors will be considered as column vectors.

maxiter Maximum number of iterations allowed; default: 100.

tol Tolerance used for stopping the iteration.

#### **Details**

Estimate the 2-norm of the matrix M, typically used for large or sparse matrices, where the cost of calculating the norm (A) is prohibitive and an approximation to the 2-norm is acceptable.

Theoretically, the 2-norm of a matrix M is defined as

$$||M||_2 = \max \frac{||M*x||_2}{||x||_2}$$
 for all  $x \neq 0$ 

where  $||.||_2$  is the Euclidean/Frobenius norm.

### Value

2-norm of the matrix as a positive real number.

### Note

If feasible, an accurate value of the 2-norm would simply be calculated as the maximum of the singular values (which are all positive):

```
max(svd(M)\$d)
```

### References

normest(magic(100)) # 500050
```

nthroot

Real nth Root

## Description

Compute the real n-th root of real numbers.

# Usage

```
nthroot(x, n)
```

## **Arguments**

x numeric vector or matrix

n positive integer specifying the exponent 1/n.

### **Details**

Computes the n-th root real numbers of a numeric vector x, while  $x^{(1/n)}$  will return NaN for negative numbers, even in case n is odd. If some numbers in x are negative, n must be odd. (This is different in Octave)

## Value

Returns a numeric vector of solutions to  $x^{1/n}$ .

## See Also

sqrt

```
nthroot(c(1, -2, 3), 3) #=> 1.000000 -1.259921 1.442250 (-2)^(1/3) #=> NaN
```

244 nullspace

nullspace

Kernel or Nullspace

## **Description**

Kernel of the linear map defined by matrix M.

### Usage

```
nullspace(M)
null(M)
```

### **Arguments**

М

Numeric matrix; vectors will be considered as column vectors.

#### **Details**

The kernel (aka null space/nullspace) of a matrix M is the set of all vectors x for which Ax=0. It is computed from the QR-decomposition of the matrix.

null is simply an alias for nullspace – and the Matlab name.

## Value

If M is an n-by-m (operating from left on m-dimensional column vectors), then N=nullspace(M) is a m-by-k matrix whose columns define a (linearly independent) basis of the k-dimensional kernel in  $R^m$ .

If the kernel is only the null vector (0 0 ... 0), then NULL will be returned.

As the rank of a matrix is also the dimension of its image, the following relation is true:

```
m = dim(nullspace(M)) + rank(M)
```

#### Note

The image of M can be retrieved from orth().

### References

N <- nullspace(M)
            [,1]
                        [,2]
                                  [,3]
# [1,] 0.4082483 -0.8164966 0.4082483
M1 \leftarrow matrix(1:6, 2, 3) \# of rank 2
M2 \leftarrow t(M1)
nullspace(M1)
                          # corresponds to 1 -2 1
nullspace(M2)
                          # NULL, i.e. 0 0
M <- magic(5)
                         #=> 5
Rank(M)
nullspace(M)
                          #=> NULL, i.e. 0 0 0 0 0
```

numderiv

Richardson's Numerical Derivative

### **Description**

Richardson's method applied to the computation of the numerical derivative.

### Usage

```
numderiv(f, x0, maxiter = 16, h = 1/2, ..., tol = .Machine$double.eps)
numdiff(f, x, maxiter = 16, h = 1/2, ..., tol = .Machine$double.eps)
```

### **Arguments**

f function to be differentiated.

x0, x point(s) at which the derivative is to be computed.

maxiter maximum number of iterations.

h starting step size, should be the default h=0.5.

tol relative tolerance.

... variables to be passed to function f.

#### **Details**

numderiv returns the derivative of f at x0, where x0 must be a single scalar in the domain of the function.

numdiff is a vectorized form of numderiv such that the derivatives will be returned at all points of the vector x.

246 numel

#### Value

Numeric scalar or vector of approximated derivatives.

#### Note

See grad in the 'numDeriv' package for another implementation of Richardson's method in the context of numerical differentiation.

ode23

Non-stiff (and stiff) ODE solvers

## **Description**

Runge-Kutta (2, 3)-method with variable step size, resp. (4,5)-method with Dormand-Price coefficients, or (7,8)-pairs with Fehlberg coefficients. The function f(t,y) has to return the derivative as a column vector.

## Usage

## Arguments

f	function in the differential equation $y'=f(x,y)$ ; defined as a function $R\times R^m\to R^m$ , where $m$ is the number of equations.
t0, tfinal	start and end points of the interval.
y0	starting values as column vector; for $\boldsymbol{m}$ equations $u 0$ needs to be a vector of length $m.$
jac	jacobian of $f$ as a function of $x$ alone; if not specified, a finite difference approximation will be used.
rtol, atol	relative and absolute tolerance.
hmax	maximal step size, default is (tfinal -t0)/10.
	Additional parameters to be passed to the function.

248 ode23

#### **Details**

ode23 is an integration method for systems of ordinary differential equations using second and third order Runge-Kutta-Fehlberg formulas with automatic step-size.

ode23s can be used to solve a stiff system of ordinary differential equations, based on a modified Rosenbrock triple method of order (2,3); See section 4.1 in [Shampine and Reichelt].

ode45 implements Dormand-Prince (4,5) pair that minimizes the local truncation error in the 5thorder estimate which is what is used to step forward (local extrapolation). Generally it produces more accurate results and costs roughly the same computationally.

ode78 implements Fehlberg's (7.8) pair and is a 7th-order accurate integrator therefore the local error normally expected is  $O(h^8)$ . However, because this particular implementation uses the 8th-order estimate for xout (i.e. local extrapolation) moving forward with the 8th-order estimate will yield errors on the order of  $O(h^9)$ . It requires 13 function evaluations per integration step.

#### Value

List with components t for grid (or 'time') points between t0 and tfinal, and y an n-by-m matrix with solution variables in columns, i.e. each row contains one time stamp.

odregress

Orthogonal Distance Regression

## **Description**

Orthogonal Distance Regression (ODR, a.k.a. total least squares) is a regression technique in which observational errors on both dependent and independent variables are taken into account.

## Usage

```
odregress(x, y)
```

### **Arguments**

x matrix of independent variables.

y vector representing dependent variable.

#### **Details**

The implementation used here is applying PCA resp. the singular value decomposition on the matrix of independent and dependent variables.

#### Value

Returns list with components coeff linear coefficients and intercept term, ssq sum of squares of orthogonal distances to the linear line or hyperplane, err the orthogonal distances, fitted the fitted values, resid the residuals, and normal the normal vector to the hyperplane.

#### Note

The "geometric mean" regression not implemented because questionable.

orth

252 pade

### **Description**

Range space or image of a matrix.

# Usage

```
orth(M)
```

## **Arguments**

М

Numeric matrix; vectors will be considered as column vectors.

### **Details**

B=orth(A) returns an orthonormal basis for the range of A. The columns of B span the same space as the columns of A, and the columns of B are orthogonal to each other.

The number of columns of B is the rank of A.

#### Value

Matrix of orthogonal columns, spanning the image of M.

pade

Pade Approximation

## Description

A Pade approximation is a rational function (of a specified order) whose power series expansion agrees with a given function and its derivatives to the highest possible order.

## Usage

```
pade(p1, p2 = c(1), d1 = 5, d2 = 5)
```

pade 253

# Arguments

p1	polynomial representing or approximating the function, preferably the Taylor series of the function around some point.
p2	if present, the function is given as p1/p2.
d1	the degree of the numerator of the rational function.
d2	the degree of the denominator of the rational function.

### **Details**

The relationship between the coefficients of p1 (and p2) and r1 and r2 is determined by a system of linear equations. The system is then solved by applying the pseudo-inverse pinv for for the left-hand matrix.

### Value

List with components r1 and r2 for the numerator and denominator polynomials, i.e. r1/r2 is the rational approximation sought.

### Note

In general, errors for Pade approximations are smallest when the degrees of numerator and denominator are the same or when the degree of the numerator is one larger than that of the denominator.

pchip

Hermitean Interpolation Polynomials

# Description

Piecewise Cubic Hermitean Interpolation Polynomials.

# Usage

```
pchip(xi, yi, x)
pchipfun(xi, yi)
```

pchip 255

# **Arguments**

```
xi, yix- and y-coordinates of supporting nodes.xx-coordinates of interpolation points.
```

### **Details**

pchip is a 'shape-preserving' piecewise cubic Hermite polynomial approach that apptempts to determine slopes such that function values do not overshoot data values. pchipfun is a wrapper around pchip and returns a function. Both pchip and the function returned by pchipfun are vectorized.

xi and yi must be vectors of the same length greater or equal 3 (for cubic interpolation to be possible), and xi must be sorted. pchip can be applied to points outside [min(xi), max(xi)], but the result does not make much sense outside this interval.

### Value

Values of interpolated data at points x.

### Author(s)

Copyright of the Matlab version from Cleve Moler in his book "Numerical Computing with Matlab", Chapter 3 on Interpolation. R Version by Hans W. Borchers, 2011.

256 peaks

peaks

Peaks Function (Matlab Style)

# **Description**

An example functions in two variables, with peaks.

# Usage

```
peaks(v = 49, w)
```

# **Arguments**

v vector, whose length will be used, or a natural number.w another vector, will be used in meshgrid(x,y).

#### **Details**

peaks is a function of two variables, obtained by translating and scaling Gaussian distributions, which is useful for demonstrating three-dimensional plots.

### Value

Returns three matrices as a list with X, Y, and Z components, the first two being the result of the meshgrid function, and Z the application of the following function at the points of X and Y:

```
z <-3 * (1-x)^2 * exp(-(x^2) - (y+1)^2) -10 * (x/5 - x^3 - y^5) * exp(-x^2 - y^2) -1/3 * exp(-(x+1)^2 - y^2)
```

# Note

The variant that peaks () will display the 3-dim. graph as in Matlab is not yet implemented.

### See Also

meshgrid

```
peaks(3)
## Not run:
P <- peaks()
x <- P$X[1,]; y <- P$Y[, 1]
persp(x, y, P$Z)
## End(Not run)</pre>
```

perms 257

perms

Generate Permutations

# Description

Generates all permutations of a vector a.

# Usage

```
perms(a)
```

# Arguments

а

numeric vector of some length n

### **Details**

If a is a vector of length n, generate all permutations of the elements in a as a matrix of size  $n! \times n$  where each row represents one permutation.

A matrix will be expanded as vector.

### Value

matrix of permutations of the elements of a

# Note

Not feasible for length(a) > 10.

258 piecewise

piecewise

Piecewise Linear Function

# Description

Compute zeros and area of a piecewise linear function.

# Usage

```
piecewise(x, y, abs = FALSE)
```

# Arguments

x, y	x- and y-coordinates of points defining the piecewise linear function
abs	logical; shall the integral or the total area between the x-axis and the function be
	calculated

# **Details**

Compute zeros and integral resp. area of a piecewise linear function given by points with x and y as coordinates.

# Value

Returns a list with the integral or area as first element and the vector as all zeroes as second.

# See Also

trapz

```
x <- c(0, 2, 3, 4, 5)

y <- c(2, -2, 0, -2, 0)

piecewise(x, y)

piecewise(x, y, abs=TRUE)
```

pinv 259

pinv

Pseudoinverse or Generalized Inverse

# Description

Computes the Moore-Penrose generalized inverse of a matrix.

### Usage

```
pinv(A, tol=.Machine$double.eps^(2/3))
```

# **Arguments**

A real or complex matrix

tol tolerance used for assuming an eigenvalue is zero.

### **Details**

Compute the generalized inverse B of a matrix A using the singular value decomposition svd(). This generalized invers is characterized by this equation: A %\*% B %\*% A == A

The pseudoinverse B solves the problem to minimize |Ax - b| by setting x = Bb

```
s <-svd(A)
D <-diag(s\$d)
Dinv <-diag(1/s\$d)
U <-s\$u; V <-s\$v
X = V Dinv t(U)</pre>
```

Thus B is computed as s\$v %\*% diag(1/s\$d) %\*% t(s\$u).

## Value

The pseudoinverse of matrix A.

### Note

The pseudoinverse or 'generalized inverse' is also provided by the function ginv() in package 'MASS'. It is included in a somewhat simplified way to be independent of that package.

### **Examples**

```
A <- matrix(c(7,6,4,8,10,11,12,9,3,5,1,2), 3, 4)
b <- apply(A, 1, sum) # 32 16 20 row sum
x <- pinv(A) %*% b
A %*% x #=> 32 16 20 as column vector
```

plotyy

Plotting Two y-Axes

# Description

Line plot with y-axes on both left and right side.

# Usage

# Arguments

x1, x2	x-coordinates for the curves
y1, y2	the y-values, with ordinates y1 left, y2 right.
gridp	logical; shall a grid be plotted.
box.col	color of surrounding box.
type	type of the curves, line or points (for both data).
lwd	line width (for both data).
lty	line type (for both data).
xlab, ylab	text below and on the left.
main	main title of the plot.
col.y1, col.y2	colors to be used for the lines or points.
	additional plotting parameters.

### **Details**

Plots y1 versus x1 with y-axis labeling on the left and plots y2 versus x2 with y-axis labeling on the right.

The x-values should not be too far appart. To exclude certain points, use NA values. Both curves will be line or point plots, and have the same line type and width.

# Value

Generates a graph, no return values.

y2 <- 0.8*exp(-0.5*x)*sin(10*x)

plotyy(x, y1, x, y2, main = "Two-ordinates Plot")
## End(Not run)</pre>
```

poisson2disk

Poisson Disk Sampling

### Description

Approximate Poisson disk distribution of points in a rectangle.

### Usage

```
poisson2disk(n, a = 1, b = 1, m = 10, info = TRUE)
```

### **Arguments**

n number of points to generate in a rectangle.
a, b width and height of the rectangle
m number of points to try in each step.
info shall additional info be printed.

### **Details**

Realizes Mitchell's best-candidate algorithm for creating a Poisson disk distribution on a rectangle. Can be used for sampling, and will be more appropriate in some sampling applications than uniform sampling or grid-like sampling.

With m = 1 uniform sampling will be generated.

### Value

Returns the points as a matrix with two columns for x- and y-coordinates. Prints the minimal distance between points generated.

### Note

Bridson's algorithm for Poisson disk sampling may be added later as an alternative. Also a variant that generates points in a circle.

262 polar

# **Examples**

polar

Polar Coordinate Plot (Matlab Style)

# **Description**

The polar function accepts polar coordinates, plots them in a Cartesian plane, and draws the polar grid on the plane.

# Usage

### **Arguments**

```
type type of the plot, lines, points, or no plotting.

col color of the graph.

grcol, bxcol color of grid and box around the plot.

main plot title.

add logical; if true, the graph will be plotted into the coordinate system of an existing plot.

... plotting parameters to be passed to the points function.
```

Poly 263

### **Details**

polar (theta, rho) creates a polar coordinate plot of the angle theta versus the radius rho. theta is the angle from the x-axis to the radius vector specified in radians; rho is the length of the radius vector.

# Value

Generates a plot; no returns.

### **Examples**

```
## Not run:
t <- deg2rad(seq(0, 360, by = 2))
polar(t, cos(2*t), bxcol = "white", main = "Sine and Cosine")
polar(t, sin(2*t), col = "red", add = TRUE)
## End(Not run)</pre>
```

Poly

Define Polynomial by Roots

### **Description**

Define a polynomial by its roots.

### Usage

```
Poly(x)
```

# **Arguments**

Х

vector or square matrix, real or complex

# **Details**

Computes the characteristic polynomial of an (n x n)-Matrix.

If x is a vector, Poly(x) is the vector of coefficients of the polynomial whose roots are the elements of x.

### Value

Vector representing a polynomial.

### Note

In Matlab/Octave this function is called poly().

264 poly2str

```

# **Examples**

```
Poly(c(1, -1, 1i, -1i)) # Solves x^4 - 1 = 0 # Wilkinson's example: roots(Poly(1:20))
```

poly2str

Print Polynomial

# Description

Print polynomial as a character string.

# Usage

```
poly2str(p, svar = "x", smul = "*", d = options("digits")$digits)
```

# **Arguments**

p	numeric vector representing a polynomial
svar	character representing the unknown, default x.
smul	multiplication symbol, default *.
d	significant digits, default options("digits").

### **Details**

Simple string manipulation.

# Value

Returns the usual string representing a polynomial in mathematics.

```
poly2str(c(0))
poly2str(c(1, -1, 1, -1, 1))
poly2str(c(0, 1e-6, 1e6), d = 2)
```

polyadd 265

polyadd

Adding Polynomials

# Description

Add two polynomials given as vectors.

# Usage

```
polyadd(p, q)
```

# **Arguments**

p, q

Vectors representing two polynomials.

### **Details**

Polynomial addition realized simply by multiplying and summing up all the coefficients after extending vectors to the same length.

# Value

Vector representing a polynomial.

# Note

There is no such function in Matlab or Octave.

Polynomial Approximation

# Description

Generate a polynomial approximation.

## Usage

```
polyApprox(f, a, b, n, ...)
```

## **Arguments**

f function to be approximated.

a, b end points of the interval.

n degree of the polynomial.

further variables for function f.

### **Details**

Uses the Chebyshev coefficients to derive polynomial coefficients.

### Value

List with four components:

p the approximating polynomial.

f a function evaluating this polynomial.

cheb.coeff the Chebyshev coefficients.

estim.prec the estimated precision over the given interval.

### Note

The Chebyshev approximation is optimal in the sense of the  $L^1$  norm, but not as a solution of the *minimax* problem; for this, an application of the Remez algorithm is needed.

polyarea

Area of a Polygon

# **Description**

Calculates the area and length of a polygon given by the vertices in the vectors x and y.

# Usage

```
polyarea(x, y)
poly_length(x, y)
poly_center(x, y)
poly_crossings(L1, L2)
```

# Arguments

```
    x x-coordinates of the vertices defining the polygon
    y y-coordinates of the vertices
    L1, L2 matrices of type 2xn with x- and y-coordinates.
```

268 polyarea

### **Details**

polyarea calculates the area of a polygon defined by the vertices with coordinates x and y. Areas to the left of the vertices are positive, those to the right are counted negative.

The computation is based on the Gauss polygon area formula. The polygon automatically be closed, that is the last point need not be / should not be the same as the first.

If some points of self-intersection of the polygon line are not in the vertex set, the calculation will be inexact. The sum of all areas will be returned, parts that are circulated in the mathematically negative sense will be counted as negative in this sum.

If x, y are matrices of the same size, the areas of all polygons defined by corresponding columns are computed.

poly\_center calculates the center (of mass) of the figure defined by the polygon. Self-intersections should be avoided in this case. The mathematical orientation of the polygon does not have influence on the center coordinates.

poly\_length calculates the length of the polygon

poly\_crossings calculates the crossing points of two polygons given as matrices with x- and y-coordinates in the first and second row. Can be used for finding the crossing points of parametrizised curves.

#### Value

Area or length of the polygon resp. sum of the enclosed areas; or the coordinates of the center of gravity.

poly\_crossings returns a matrix with column names x and y representing the crossing points.

polyder

Derivative of Polynomial

### **Description**

Differentiate polynomials.

# Usage

```
polyder(p, q)
```

### **Arguments**

```
p polynomial p given as a vector
q polynomial p given as a vector
```

270 polyfit,polyfix

### **Details**

Calculates the derivative of polynomials and polynomial products.

polyder(p) returns the derivative of p while polyder(p, q) returns the derivative of the product of the polynomials p and q.

### Value

a vector representing a polynomial

### See Also

```
polyval, polyint
```

## **Examples**

```
polyder(c(3, 6, 9), c(1, 2, 0)) # 12 36 42 18
```

polyfit,polyfix

Fitting by Polynomial

### Description

Polynomial curve fitting

# Usage

```
polyfit(x, y, n)
polyfix(x, y, n, xfix, yfix)
```

### Arguments

x x-coordinates of pointsy y-coordinates of points

n degree of the fitting polynomial

xfix, yfix x- and y-coordinates of points to be fixed

### **Details**

polyfit finds the coefficients of a polynomial of degree n fitting the points given by their x, y coordinates in a least-squares sense. In polyfit, if x, y are matrices of the same size, the coordinates are taken elementwise. Complex values are not allowed.

polyfix finds a polynomial that fits the data in a least-squares sense, but also passes exactly through all the points with coordinates xfix and yfix. Degree n should be greater or equal to the number of fixed points, but not too big to avoid 'singular matrix' or similar error messages

polyfit,polyfix 271

# Value

vector representing a polynomial.

#### Note

Please not that polyfit2 is has been removed since 1.9.3; please use polyfix instead.

272 polylog

polyint

Anti-derivative of Polynomial

# Description

Integrate polynomials.

# Usage

```
polyint(p, k)
```

# **Arguments**

p polynomial p given as a vector

k an integration constant

# **Details**

Calculates the integral, i.e. the antiderivative, of a polynomial and adds a constant of integration k if given, else 0.

# Value

a vector representing a polynomial

# See Also

```
polyval, polyder
```

# **Examples**

```
polyint(c(1, 1, 1, 1, 1), 1)
```

polylog

Polylogarithm Function

# Description

Computes the n-based polylogarithm of z:  $Li_n(z)$ .

# Usage

```
polylog(z, n)
```

polylog 273

# Arguments

z real number or vector, all entries satisfying abs(z)<1.

n base of polylogarithm, integer greater or equal -4.

### **Details**

The Polylogarithm is also known as Jonquiere's function. It is defined as

$$\sum_{k=1}^{\infty} z^k / k^n = z + z^2 / 2^n + \dots$$

The polylogarithm function arises, e.g., in Feynman diagram integrals. It also arises in the closed form of the integral of the Fermi-Dirac and the Bose-Einstein distributions.

The special cases n=2 and n=3 are called the dilogarithm and trilogarithm, respectively.

Approximation should be correct up to at least 5 digits for |z| > 0.55 and on the order of 10 digits for |z| <= 0.55.

#### Value

Returns the function value (not vectorized).

### Note

Based on some equations, see references. A Matlab implementation is available in the Matlab File Exchange.

274 polymul, polydiv

polymul, polydiv

Multiplying and Dividing Polynomials

# **Description**

Multiply or divide two polynomials given as vectors.

# Usage

```
polymul(p, q)
polydiv(p, q)
```

### **Arguments**

p, q

Vectors representing two polynomials.

#### **Details**

Polynomial multiplication realized simply by multiplying and summing up all the coefficients. Division is an alias for deconv. Polynomials are defined from highest to lowest coefficient.

### Value

Vector representing a polynomial. For division, it returns a list with 'd' the result of the division and 'r' the rest.

### Note

conv also realizes polynomial multiplication, through Fast Fourier Transformation, with the draw-back that small imaginary parts may evolve. deconv can also be used for polynomial division.

# See Also

polypow 275

polypow

Polynomial Powers

# Description

Power of a polynomial.

# Usage

```
polypow(p, n)
```

# Arguments

p vector representing a polynomial.

n positive integer, the exponent.

# **Details**

Uses polymul to multiply the polynomial p n times with itself.

# Value

Vector representing a polynomial.

# Note

There is no such function in Matlab or Octave.

### See Also

```
polymul
```

276 polytrans, polygcf

```
polytrans, polygcf Polynomial Transformations
```

# **Description**

Transform a polynomial, find a greatest common factor, or determine the multiplicity of a root.

# Usage

```
polytrans(p, q)
polygcf(p, q, tol = 1e-12)
```

### **Arguments**

```
p, q vectors representing two polynomials.
tol tolerance for coefficients to tolerate.
```

### **Details**

Transforms polynomial p replacing occurences of x with another polynomial q in x.

Finds a greatest common divisor (or factor) of two polynomials. Determines the multiplicity of a possible root; returns 0 if not a root. This is in general only true to a certain tolerance.

# Value

polytrans and polygcf return vectors representing polynomials. rootsmult returns a natural number (or 0).

### Note

There are no such functions in Matlab or Octave.

polyval, polyvalm 277

polyval, polyvalm

Evaluating a Polynomial

### **Description**

Evaluate polynomial on vector or matrix.

# Usage

```
polyval(p, x)
polyvalm(p, A)
```

# Arguments

p vector representing a polynomial.

x vector of values where to evaluate the polynomial.

A matrix; needs to be square.

### **Details**

polyval valuates the polynomial given by p at the values specified by the elements of x. If x is a matrix, the polynomial will be evaluated at each element and a matrix returned.

polyvalm will evaluate the polynomial in the matrix sense, i.e., matrix multiplication is used instead of element by element multiplication as used in 'polyval'. The argument matrix A must be a square matrix.

## Value

Vector of values, resp. a matrix.

### See Also

```
poly, roots
```

```
# Evaluate 3 x^2 + 2 x + 1 at x = 5, 7, and 9

p = c(3, 2, 1);

polyval(p, c(5, 7, 9)) # 86 162 262

# Apply the characteristic polynomial to its matrix

A <- pascal(4)

p <- pracma::Poly(A) # characteristic polynomial of A

polyvalm(p, A) # almost zero 4x4-matrix
```

278 ppfit

pow2

Base 2 Power

# Description

Power with base 2.

# Usage

```
pow2(f, e)
```

# **Arguments**

f numeric vector of factors

e numeric vector of exponents for base 2

### **Details**

Computes the expression  $f * 2^e$ , setting e to f and f to 1 in case e is missing. Complex values are only processed if e is missing.

# Value

Returns a numeric vector computing  $f 2^e$ .

### See Also

```
nextpow2
```

# **Examples**

```
pow2(c(0, 1, 2, 3))  #=> 1 2 4 8

pow2(c(0, -1, 2, 3), c(0,1,-2,3))  #=> 0.0 -2.0 0.5 24.0

pow2(1i)  #=> 0.7692389+0.6389613i
```

ppfit

Piecewise Polynomial Fit

# Description

Piecewise linear or cubic fitting.

# Usage

```
ppfit(x, y, xi, method = c("linear", "cubic"))
```

ppfit 279

### Arguments

```
    x, y
    x-, y-coordinates of given points.
    xi
    x-coordinates of the choosen support nodes.
    method
    interpolation method, can be 'constant', 'linear', or 'cubic' (i.e., 'spline').
```

### **Details**

ppfit fits a piece-wise polynomial to the input independent and dependent variables,x and y, respectively. A weighted linear least squares solution is provided. The weighting vector w must be of the same size as the input variables.

### Value

Returns a pp (i.e., piecewise polynomial) structure.

### Note

Following an idea of Copyright (c) 2012 Ben Abbott, Martin Helm for Octave.

## End(Not run)
```

280 ppval

ppval

Piecewise Polynomial Structures

# Description

Make or evaluate a piecewise polynomial.

## Usage

```
mkpp(x, P)
ppval(pp, xx)
```

# **Arguments**

		1
V	increasing vector of real num	hare
^	increasing vector of real num	ours.

P matrix containing the coefficients of polynomials in each row.

pp a piecewise polynomial structure, generated by mkpp.

xx numerical vector

### **Details**

pp<-mkpp(x,P) builds a piecewise polynomial from its breaks x and coefficients P. x is a monotonically increasing vector of length L+1, and P is an L-by-k matrix where each row contains the coefficients of the polynomial of order k, from highest to lowest exponent, on the interval [x[i],x[i+1]).

ppval(pp, xx) returns the values of the piecewise polynomial pp at the entries of the vector xx. The first and last polynomial will be extended to the left resp. right of the interval [x[1],x[L+1]).

### Value

mkpp will return a piecewise polynomial structure, that is a list with components breaks=x, pieces=P, order=k and dim=1 for scalar-valued functions.

# Note

Matlab allows to generate vector-valued piecewise polynomials. This may be included in later versions.

lines(x100, ypp, col="red")

## End(Not run)</pre>
```

primes

Prime Numbers

# **Description**

Generate a list of prime numbers less or equal n, resp. between n1 and n2.

# Usage

```
primes(n)
```

### **Arguments**

n

nonnegative integer greater than 1.

### **Details**

The list of prime numbers up to n is generated using the "sieve of Erasthostenes". This approach is reasonably fast, but may require a lot of main memory when n is large.

In double precision arithmetic integers are represented exactly only up to 2^53 - 1, therefore this is the maximal allowed value.

### Value

vector of integers representing prime numbers

### See Also

procrustes

Solving the Procrustes Problem

# Description

procrustes solves for two matrices A and B the 'Procrustes Problem' of finding an orthogonal matrix Q such that A-B\*Q has the minimal Frobenius norm.

kabsch determines a best rotation of a given vector set into a second vector set by minimizing the weighted sum of squared deviations. The order of vectors is assumed fixed.

### Usage

```
procrustes(A, B)
kabsch(A, B, w = NULL)
```

procrustes 283

### **Arguments**

A, B two numeric matrices of the same size.w weights, influence the distance of points

### **Details**

The function procrustes (A,B) uses the svd decomposition to find an orthogonal matrix Q such that A-B\*Q has a minimal Frobenius norm, where this norm for a matrix C is defined as sqrt(Trace(t(C)\*C)), or norm(C, F') in R.

Solving it with B=I means finding a nearest orthogonal matrix.

kabsch solves a similar problem and uses the Procrustes procedure for its purpose. Given two sets of points, represented as columns of the matrices A and B, it determines an orthogonal matrix U and a translation vector R such that U\*A+R-B is minimal.

### Value

procrustes returns a list with components P, which is B\*Q, then Q, the orthogonal matrix, and d, the Frobenius norm of A-B\*Q.

kabsch returns a list with U the orthogonal matrix applied, R the translation vector, and d the least root mean square between U\*A+R and B.

### Note

The kabsch function does not take into account scaling of the sets, but this could easily be integrated.

284 psi

psi

Psi (Polygamma) Function

# Description

Arbitrary order Polygamma function valid in the entire complex plane.

### **Usage**

```
psi(k, z)
```

# **Arguments**

k order of the polygamma function, whole number greater or equal 0.

z numeric complex number or vector.

# **Details**

Computes the Polygamma function of arbitrary order, and valid in the entire complex plane. The polygamma function is defined as

$$\psi(n,z) = \frac{d^{n+1}}{dz^{n+1}} \log(\Gamma(z))$$

If n is 0 or absent then psi will be the Digamma function. If n=1,2,3,4,5 etc. then psi will be the tri-, tetra-, penta-, hexa-, hepta- etc. gamma function.

### Value

Returns a complex number or a vector of complex numbers.

qpspecial, qpsolve 285

qpspecial, qp	psolve	Special	Ouadratic	<b>Programming</b>	Solver
---------------	--------	---------	-----------	--------------------	--------

# **Description**

Solves a special Quadratic Programming problem.

### Usage

```
qpspecial(G, x, maxit = 100)

qpsolve(d, A, b, meq = 0, tol = 1e-07)
```

### **Arguments**

G	m x n-matrix.
X	column vector of length $n$ , the initial (feasible) iterate; if not present (or requirements on $x0$ not met), $x0$ will be found.
maxit	maximum number of iterates allowed; default 100.
d	Linear term of the quadratic form.
A, b	Linear equality and inequality constraints.
meq	First meq rows are used as equality constraints.
tol	Tolerance used for stopping the iteration.

# **Details**

```
\ensuremath{\mathsf{qpspecial}} solves the special QP problem:
```

```
\min q(x) = || G*x ||_2^2 = x'*(G'*G)*x
s.t. \sup(x) = 1
and x \ge 0
```

The problem corresponds to finding the smallest vector (2-norm) in the convex hull of the columns of G.

qpsolve solves the more general QP problem:

```
min q(x) = 0.5 t(x)*x - d x
s.t. A x >= b
with A x = b for the first meg rows.
```

### Value

Returns a list with the following components:

- x optimal point attaining optimal value;
- d = G\*x smallest vector in the convex hull;
- q optimal value found, = t(d) %\*% d;

286 qpspecial, qpsolve

- niter number of iterations used;
- info error number:
  - = 0: everything went well, q is optimal,
  - = 1: maxit reached and final x is feasible,
  - = 2: something went wrong.

### Note

x may be missing, same as if requirements are not met; may stop with an error if x is not feasible.

qrSolve

LSE Solution

### **Description**

Systems of linear equations via QR decomposition.

# Usage

```
qrSolve(A, b)
```

# **Arguments**

```
A numerical matrix with nrow(A)>=ncol(A).
b numerical vector with length(b) == nrow(A).
```

### **Details**

Solves (overdetermined) systems of linear equations via QR decomposition.

### Value

The solution of the system as vector.

```

288 quad

quad	Adaptive Simpson Quadrature	

# Description

Adaptive quadrature of functions of one variable over a finite interval.

### Usage

```
quad(f, xa, xb, tol = .Machine$double.eps^0.5, trace = FALSE, ...)
```

# **Arguments**

f	a one-dimensional function; needs to be vectorized.
xa	lower limit of integration; must be finite
xb	upper limit of integration; must be finite
tol	accuracy requested.
trace	logical; shall a trace be printed?
	additional arguments to be passed to f.

# **Details**

Realizes adaptive Simpson quadrature in R through recursive calls.

The function f needs to be vectorized though this could be changed easily. quad is not suitable for functions with singularities in the interval or at end points.

# Value

A single numeric value, the computed integral.

### Note

More modern adaptive methods based on Gauss-Kronrod or Clenshaw-Curtis quadrature are now generally preferred.

### Author(s)

quad2d

2-d Gaussian Quadrature

# Description

Two-dimensional Gaussian Quadrature.

## Usage

```
quad2d(f, xa, xb, ya, yb, n = 32, ...)
```

# Arguments

f	function of two variables; needs to be vectorized.
xa, ya	lower limits of integration; must be finite.
xb, yb	upper limits of integration; must be finite.
n	number of nodes used per direction.
	additional arguments to be passed to f.

#### **Details**

Extends the Gaussian quadrature to two dimensions by computing two sets of nodes and weights (in x- and y-direction), evaluating the function on this grid and multiplying weights appropriately.

The function f needs to be vectorized in both variables such that f(X, Y) returns a matrix when X an Y are matrices (of the same size).

quad is not suitable for functions with singularities.

290 quadcc

#### Value

A single numerical value, the computed integral.

#### Note

The extension of Gaussian quadrature to two dimensions is obvious, but see also the example 'integral2d.m' at Nick Trefethens "10 digits 1 page".

## **Examples**

quadcc

Adaptive Clenshaw-Curtis Quadrature

### Description

Adaptive Clenshaw-Curtis Quadrature.

### Usage

```
quadcc(f, a, b, tol = .Machine$double.eps^0.5, ...)
```

# **Arguments**

```
f integrand as function, may have singularities at the endpoints.

a, b endpoints of the integration interval.

tol relative tolerence.

Additional parameters to be passed to the function f.
```

quadgk 291

### **Details**

Adaptive version of the Clenshaw-Curtis quadrature formula with an (4, 8)-point erroe term.

#### Value

List with two components, value the value of the integral and the relative error error.

## See Also

```
clenshaw_curtis
```

## **Examples**

```
## Not run:
## Dilogarithm function
flog <- function(t) log(1-t)/t
quadcc(flog, 1, 0, tol = 1e-12)
# 1.644934066848128 - pi^2/6 < 1e-13
## End(Not run)</pre>
```

quadgk

Adaptive Gauss-Kronrod Quadrature

### **Description**

Adaptive Gauss-Kronrod Quadrature.

## Usage

```
quadgk(f, a, b, tol = .Machine$double.eps^0.5, ...)
```

## **Arguments**

f integrand as function; needs to be vectorized, but may have singularities at the endpoints.

a, b endpoints of the integration interval.

tol relative tolerence.

... Additional parameters to be passed to the function f.

#### Details

Adaptive version of the (7, 15)-point Gauss-Kronrod quadrature formula, where in each recursion the error is taken as the difference between these two estimated integrals.

The function f must be vectorized, though this will not be checked and may lead to strange errors. If it is not, use F = Vectorize(f).

292 quadgr

### Value

Value of the integration. The relative error should be of the same order of magnitude as the relative tolerance (or much smaller).

#### Note

Uses the same nodes and weights as the quadQK15 procedure in the QUADPACK library.

#### See Also

```
gauss_kronrod
```

## **Examples**

```
## Dilogarithm function
flog <- function(t) log(1-t)/t
quadgk(flog, 1, 0, tol = 1e-12)
# 1.644934066848128 - pi^2/6 < 1e-13</pre>
```

quadgr

Gaussian Quadrature with Richardson Extrapolation

## **Description**

Gaussian 12-point quadrature with Richardson extrapolation.

### Usage

```
quadgr(f, a, b, tol = .Machine$double.eps^(1/2), ...)
```

# Arguments

f integrand as function, may have singularities at the endpoints.

a, b endpoints of the integration interval.

tol relative tolerence.

... Additional parameters to be passed to the function f.

#### **Details**

quadgr uses a 12-point Gauss-Legendre quadrature. The error estimate is based on successive interval bisection. Richardson extrapolation accelerates the convergence for some integrals, especially integrals with endpoint singularities.

Through some preprocessing infinite intervals can also be handled.

### Value

List with value and rel.err.

quadinf 293

### Author(s)

# 2.07167616395054e-13</pre>
```

quadinf

Infinite Integrals

### **Description**

Iterative quadrature of functions over finite, semifinite, or infinite intervals.

#### **Usage**

```
quadinf(f, xa, xb, tol = 1e-12, ...)
```

## Arguments

f	univariate function; needs not be vectorized.
xa	lower limit of integration; can be infinite
xb	upper limit of integration; can be infinite
tol	accuracy requested.
	additional arguments to be passed to f.

#### **Details**

quadinf implements the 'double exponential method' for fast numerical integration of smooth real functions on finite intervals. For infinite intervals, the tanh-sinh quadrature scheme is applied, that is the transformation g(t)=tanh(pi/2\*sinh(t)).

Please note that this algorithm does work very accurately for 'normal' function, but should not be applied to (heavily) oscillating functions. The maximal number of iterations is 7, so if this is returned the iteration may not have converged.

The integrand function needs not be vectorized.

294 quadl

### Value

A list with components Q the integral value, relerr the relative error, and niter the number of iterations.

#### Note

See also my remarks on R-help in September 2010 in the thread "bivariate vector numerical integration with infinite range".

quadl

Adaptive Lobatto Quadrature

## **Description**

Adaptive quadrature of functions of one variable over a finite interval.

# Usage

```
quadl(f, xa, xb, tol = .Machine$double.eps^0.5, trace = FALSE, ...)
```

quadl 295

## **Arguments**

f	a one-dimensional function; needs to be vectorized.
xa	lower limit of integration; must be finite
xb	upper limit of integration; must be finite
tol	accuracy requested.
trace	logical; shall a trace be printed?
	additional arguments to be passed to f.

### **Details**

Realizes adaptive Lobatto quadrature in R through recursive calls.

The function f needs to be vectorized though this could be changed easily.

#### Value

A single numeric value, the computed integral.

### Note

Compared to Gaussian quadrature, Lobatto integration include the end points of the integration interval. It is accurate for polynomials up to degree 2n-3, where n is the number of integration points.

### Author(s)

quadprog

Quadratic Programming

# Description

Solves quadratic programming problems with linear and box constraints.

## Usage

# Arguments

С	symmetric matrix, representing the quadratic term.
d	vector, representing the linear term.
Α	matrix, represents the linear constraint coefficients.
b	vector, constant vector in the constraints.
Aeq	matrix, linear equality constraint coefficients.
beq	vector, constant equality constraint vector.
lb	elementwise lower bounds.
ub	elementwise upper bounds.

## **Details**

Finds a minimum for the quadratic programming problem specified as:

$$min1/2x'Cx + d'x$$

such that the following constraints are satisfied:

$$Ax <= b$$

$$Aeqx = beq$$

$$lb <= x <= ub$$

The matrix should be symmetric and positive definite, in which case the solution is unique, indicated when the exit flag is 1.

For more information, see ?solve.QP.

quadprog 297

### Value

Returns a list with components

```
xmin minimum solution, subject to all bounds and constraints.fval value of the target expression at the arg minimum.eflag exit flag.
```

#### Note

This function is wrapping the active set quadratic solver in the quadprog package: quadprog::solve.QP, combined with a more MATLAB-like API interface.

quadv

Vectorized Integration

# Description

Vectorized adaptive Simpson integration.

## Usage

```
quadv(f, a, b, tol = .Machine$double.eps^(1/2), ...)
```

## **Arguments**

f	univariate, vector-valued function; need not be vectorized.
a, b	endpoints of the integration interval.
tol	acuracy required for the recursion step.
	further parameters to be passed to the function f.

### **Details**

Recursive version of the adaptive Simpson quadrature, recursion is based on the maximum of all components of the function calls.

quad is not suitable for functions with singularities in the interval or at end points.

quiver 299

### Value

Returns a list with components Q the integral value, fcnt the number of function calls, and estim.prec the estimated precision that normally will be much too high.

### See Also

quad

## **Examples**

quiver

Quiver or Velocity Plot

## Description

A quiver plot displays velocity vectors as arrows with components (u,v) at the points (x,y).

### Usage

## **Arguments**

```
    x, y
    x,y-coordinates of start points of the arrows.
    u, v
    x,y-coordinates of start points.
    scale
    scales the length of the arrows.
    angle
    angle between shaft and edge of the arrows.
```

300 rand

```
length length of the arrow edges.... more options presented to the arrows primitive.
```

### **Details**

The matrices x,y,u,v must all be the same size and contain corresponding position and velocity components. However, x and y can also be vectors.

### Value

Opens a graph window and plots the velocity vectors.

## See Also

```
vectorfield, arrows
```

rand

Create Random Matrices

## **Description**

Create random matrices or random points in a unit circle (Matlab style).

# Usage

```
rand(n = 1, m = n)
randn(n = 1, m = n)
randi(imax, n = 1, m = n)
randsample(n, k, w = NULL, replacement = FALSE)
rands(n = 1, N = 1, r = 1)
randp(n = 1, r = 1)
```

# Arguments

n, m	integers specifying the size of the matrix
imax	integer or pair of integers
k	number of elements to return.
W	weight vector, used for discrete probabilities.
replacement	logical; sampling with or without replacement.
N	dimension of a shere, N=1 for the unit circle
r	radius of circle, default 1.

rand 301

#### **Details**

rand(), randn(), randi() create random matrices of size n x m, where the default is square matrices if m is missing.

rand() uses the uniform distribution on ]0,1[, while randn() uses the normal distribution with mean 0 and standard deviation 1.

randi() generates integers between imax[1] and imax[2] resp. 1 and imax, if imax is a scalar.

randsample() samples k elements from 1:n, with or without replacement, or returns a weighted sample (with replacement), using the weight vector w for probabilities.

rands() generates uniformly random points on an N-sphere in the N+1-dimensional space. To generate uniformly random points in the N-dim. unit cube, take points in  $S^{N-1}$  und multiply with unif(n)^(1/(N-1)).

randp() generates uniformly random points in the unit circle (or in a circle of radius r).

### Value

Matrices of size nxm resp. a vector of length n.

randp() returns a pair of values representing a point in the circle, or a matrix of size (n,2). rands() returns a matrix of size (n,N+1) with all rows being vectors of length 1.

#### Note

The Matlab style of setting a seed is not available; use R style set.seed(...).

randcomb

Random Combination

# Description

Generates a random combination.

# Usage

```
randcomb(a, m)
```

# Arguments

```
a numeric vector of some length n m \qquad \qquad \text{integer with } 0 <= m <= n
```

### **Details**

Generates one random combination of the elements a of length m.

## Value

vector of combined elements of a

## Note

This behavior is different from Matlab/Octave, but does better correspond with the behavior of the perms() function.

randortho 303

randortho

Generate Random Orthonormal or Unitary Matrix

### Description

Generates random orthonormal or unitary matrix of size n.

Will be needed in applications that explore high-dimensional data spaces, for example optimization procedures or Monte Carlo methods.

### Usage

```
randortho(n, type = c("orthonormal", "unitary"))
```

#### **Arguments**

n positive integer.

type orthonormal (i.e., real) or unitary (i.e., complex) matrix.

#### **Details**

Generates orthonormal or unitary matrices Q, that is t(Q) resp t(Conj(Q)) is inverse to Q. The randomness is meant with respect to the (additively invariant) Haar measure on O(n) resp. U(n).

Stewart (1980) describes a way to generate such matrices by applying Householder transformation. Here a simpler approach is taken based on the QR decomposition, see Mezzadri (2006),

## Value

Orthogonal (or unitary) matrix Q of size n, that is Q % % t(Q) resp. Q % % t(Conj(Q)) is the unit matrix of size n.

#### Note

rortho was deprecated and eventually removed in version 2.1.7.

304 randperm

randperm

Random Permutation

# Description

Generates a random permutation.

# Usage

```
randperm(a, k)
```

## **Arguments**

a integer or numeric vector of some length n.

k integer, smaller as a or length(a).

#### **Details**

Generates one random permutation of k of the elements a, if a is a vector, or of 1:a if a is a single integer.

## Value

Vector of permuted elements of a or 1:a.

### Note

This behavior is different from Matlab/Octave, but does better correspond with the behavior of the perms() function.

## See Also

perms

```
randperm(1:6, 3)
randperm(6, 6)
randperm(11:20, 5)

Rank 305

Rank Matrix Rank

## **Description**

Provides an estimate of the rank of a matrix M.

## Usage

Rank(M)

### **Arguments**

М

Numeric matrix; vectors will be considered as column vectors.

#### **Details**

Provides an estimate of the number of linearly independent rows or columns of a matrix M. Compares an approach using QR-decomposition with one counting singular values larger than a certain tolerance (Matlab).

### Value

Matrix rank as integer between 0 and min(ncol(M), nrow(M)).

# Note

The corresponding function in Matlab is called rank, but that term has a different meaning in R.

#### References

Trefethen, L. N., and D. Bau III. (1997). Numerical Linear Algebra. SIAM, Philadelphia.

# In Rank(hilb(8)) : Rank calculation may be problematic.
```

306 rat

Continuous Fractions (Matlab Style)

# Description

Generate continuous fractions for numeric values.

## Usage

```
rat(x, tol = 1e-06)
rats(x, tol = 1e-06)
```

## Arguments

Х a numeric scalar or vector.

tol tolerance; default 1e-6 to make a nicer appearance for pi.

### **Details**

rat generates continuous fractions, while rats prints the the corresponding rational representation and returns the numeric values.

### Value

```
rat returns a character vector of string representations of continuous fractions in the format [b0;
b1, ..., b_{n-1}.
```

rats prints the rational number and returns a numeric vector.

# Note

Essentially, these functions apply contfrac.

# See Also

```
numbers::contfrac
```

## **Examples**

```
rat(pi)
rats(pi)
rat(sqrt(c(2, 3, 5)), tol = 1e-15)
rats(sqrt(c(2, 3, 5)), tol = 1e-15)
```

rat

ratinterp 307

ratinterp	Rational Interpolation	

### **Description**

Burlisch-Stoer rational interpolation.

### Usage

```
ratinterp(x, y, xs = x)
```

# Arguments

x	numeric vector; points on the x-axis; needs to be sorted; at least three points required.
У	numeric vector; values of the assumed underlying function; $\boldsymbol{x}$ and $\boldsymbol{y}$ must be of the same length.
xs	numeric vector; points at which to compute the interpolation; all points must lie between $min(x)$ and $max(x)$ .

### **Details**

The Burlisch-Stoer approach to rational interpolation is a recursive procedure (similar to the Newton form of polynomial interpolation) that produces a "diagonal" rational function, that is the degree of the numerator is either the same or one less than the degree of the denominator.

Polynomial interpolation will have difficulties if some kind of singularity exists in the neighborhood, even if the pole occurs in the complex plane. For instance, Runge's function has a pole at z=0.2i, quite close to the interval  $\left[-1,1\right]$ .

#### Value

Numeric vector representing values at points xs.

## Note

The algorithm does not yield a simple algebraic expression for the rational function found.

308 rationalfit

### **Examples**

```
## Rational interpolation of Runge's function
x <- c(-1, -0.5, 0, 0.5, 1.0)
y <- runge(x)
xs <- linspace(-1, 1)
ys <- runge(xs)
yy <- ratinterp(x, y, xs) # returns exactly the Runge function
## Not run:
plot(xs, ys, type="l", col="blue", lty = 2, lwd = 3)
points(x, y)
yy <- ratinterp(x, y, xs)
lines(xs, yy, col="red")
grid()
## End(Not run)</pre>
```

rationalfit

Rational Function Approximation

## **Description**

Fitting a rational function to data points.

## Usage

```
rationalfit(x, y, d1 = 5, d2 = 5)
```

### **Arguments**

x	numeric vector; points on the x-axis; needs to be sorted; at least three points required.
у	numeric vector; values of the assumed underlying function; x and y must be of the same length.
d1, d2	maximal degrees of numerator (d1) and denominator (d1) of the requested rational function.

#### **Details**

A rational fit is a rational function of two polynomials p1 and p2 (of user specified degrees d1 and d2) such that p1(x)/p2(x) approximates y in a least squares sense.

d1 and d2 must be large enough to get a good fit and usually d1=d2 gives good results

### Value

List with components p1 and p2 for the polynomials in numerator and denominator of the rational function.

rationalfit 309

### Note

This implementation will later be replaced by a 'barycentric rational interpolation'.

grid()
## End(Not run)
```

310 rectint

rectint

Rectangle Intersection Areas

## **Description**

Calculates the area of intersection of rectangles, specified by position vectors x and y.

## Usage

```
rectint(x, y)
```

## **Arguments**

х, у

both vectors of length 4, or both matrices with 4 columns.

### **Details**

Rectangles are specified as position vectors, that is c(x[1], x[2]) is the lower left corner, x[3] and x[4] are width and height of the rectangle. When x and y are matrices, each row is assumed to be a position vector specifying a rectangle.

### Value

Returns a scalar if x and y are vectors. If x is a n-by-4 and y a m-by-4 matrix, then it returns a n-by-m matrix R with entry (i,j) being the area rectint(x[i,j],y[j,]).

# [1] 0.0825</pre>
```

refindall 311

refi		

Find overlapping regular expression matches.

# Description

Find overlapping matches for a regular expression.

## Usage

```
refindall(s, pat, over = 1, ignorecase = FALSE)
```

## **Arguments**

s Single character string.
pat Regular expression.

over Natural number, indication how many steps to go forward after a match; defaults

to 1.

ignorecase logical, whether to ignore case.

#### **Details**

Returns the starting position of all — even overlapping — matches of the regular expression pat in the character string s.

The syntax for pattern matching has to be PERL-like.

### Value

A numeric vector with the indices of starting positions of all matches.

### Note

This effect can also be reached with the R function gregexpr(), see the example below.

#### See Also

```
regexp
```

```
refindall("ababababa", 'aba')
gregexpr('a(?=ba)', "ababababa", perl=TRUE)

refindall("AbababaBa", 'aba')
refindall("AbababaBa", 'aba', ignorecase = TRUE)
```

312 regexp

regexp	Match regular expression	
--------	--------------------------	--

## **Description**

Returns the positions of substrings that match the regular expression.

### Usage

```
regexp(s, pat, ignorecase = FALSE, once = FALSE, split = FALSE)
regexpi(s, pat, once = FALSE, split = FALSE)
```

### **Arguments**

s Character string, i.e. of length 1.

pat Matching pattern as character string.

ignorecase Logical: whether case should be ignored; default: FALSE.

once Logical: whether the first are all occurrences should be found; default: all.

split Logical: should the string be splitted at the occurrences of the pattern?; default:

# Details

no.

Returns the start and end positions and the exact value of substrings that match the regular expression. If split is choosen, the splitted strings will also be returned.

#### Value

A list with components start and end as numeric vectors indicating the start and end positions of the matches.

match contains each exact match, and split contains the character vector of splitted strings.

If no match is found all components will be NULL, except split that will contain the whole string if split = TRUE.

#### Note

This is the behavior of the corresponding Matlab function, though the signature, options and return values do not match exactly. Notice the transposed parameters s and pat compared to the corresponding R function regexpr.

### See Also

regexpr

regexprep 313

### **Examples**

```
s <- "bat cat can car COAT court cut ct CAT-scan"
pat <- 'c[aeiou]+t'
regexp(s, pat)
regexpi(s, pat)</pre>
```

regexprep

Replace string using regular expression

## Description

Replace string using regular expression.

### Usage

```
regexprep(s, expr, repstr, ignorecase = FALSE, once = FALSE)
```

# Arguments

s Single character string.

expr Regular expression to be matched.

repstr String that replaces the matched substring(s).

ignorecase logical, whether to ignore case.

once logical, shall only the first or all occurences be replaced.

#### **Details**

Matches the regular expression against the string and replaces the first or all non-overlapping occurrences with the replacement string.

The syntax for regular expression has to be PERL-like.

#### Value

String with substrings replaced.

#### Note

The Matlab/Octave variant allows a character vector. This is not possible here as it would make the return value quite complicated.

#### See Also

gsub

314 repmat

### **Examples**

```
s <- "bat cat can car COAT court cut ct CAT-scan"
pat <- 'c[aeiou]+t'
regexprep(s, pat, '---')
regexprep(s, pat, '---', once = TRUE)
regexprep(s, pat, '---', ignorecase = TRUE)</pre>
```

repmat

Replicate Matrix

# Description

Replicate and tile matrix.

## Usage

```
repmat(a, n, m = n)
```

### **Arguments**

a vector or matrix to be replicated.

n, m number of times to replicate in each dimension.

### **Details**

repmat(a,m,n) creates a large matrix consisting of an m-by-n tiling of copies of a.

### Value

Returns matrix with value a replicated to the number of times in each dimension specified. Defaults to square if dimension argument resolves to a single value.

## See Also

Reshape

Reshape 315

Reshape

Reshape Matrix

## Description

Reshape matrix or vector.

### Usage

```
Reshape(a, n, m)
```

## Arguments

```
a matrix or vector
n, m size of the result
```

#### **Details**

Reshape (a, n, m) returns the n-by-m matrix whose elements are taken column-wise from a.

An error results if a does not have n\*m elements. If m is missing, it will be calculated from n and the size of a.

### Value

Returns matrix (or array) of the requested size containing the elements of a.

## **Examples**

```
a <- matrix(1:12, nrow=4, ncol=3)
Reshape(a, 6, 2)
Reshape(a, 6) # the same
Reshape(a, 3, 4)</pre>
```

ridders

Ridders' Root Finding Method

# Description

Ridders' root finding method is a powerful variant of 'regula falsi' (and 'false position'). In reliability and speed, this method is competitive with Brent-Dekker and similar approaches.

## Usage

```
ridders(fun, a, b, maxiter = 500, tol = 1e-12, ...)
```

316 ridders

## **Arguments**

fun function whose root is to be found.

a, b left and right interval bounds.

maxiter maximum number of iterations (function calls).

tol tolerance, length of the last interval.

... additional parameters passed on to the function.

#### **Details**

Given a bracketing interval  $[x_1, x_2]$ , the method first calculates the midpoint  $x_3 = (x_1 + x_2)/2$  and the uses an updating formula

$$x_4 = x_3 + (x_3 - x_1) \frac{sgn(f(x_1) - f(x_2))f(x_3)}{\sqrt{f(x_3)^2 - f(x_1)f(x_2)}}$$

### Value

Returns a list with components

root of the function.

f. root value of the function at the found root.

niter number of iterations, or more specifically: number of function calls.

estim.prec the estimated precision, coming from the last brackett.

#### Note

See function f12 whose zero at  $\sqrt{e}$  is difficult to find exactly for all root finders.

Classical Runge-Kutta

# Description

Classical Runge-Kutta of order 4.

# Usage

```
rk4(f, a, b, y0, n)
rk4sys(f, a, b, y0, n)
```

# Arguments

f	function in the differential equation $y' = f(x, y)$ ;	
	defined as a function $R \times R^m \to R^m$ , where $m$ is the number of equations.	
a, b	endpoints of the interval.	
y0	starting values; for $m$ equations $y 0$ needs to be a vector of length $\mathbf{m}$ .	
n	the number of steps from a to b.	

### **Details**

Classical Runge-Kutta of order 4 for (systems of) ordinary differential equations with fixed step size.

## Value

List with components x for grid points between a and b and y an n-by-m matrix with solutions for variables in columns, i.e. each row contains one time stamp.

#### Note

This function serves demonstration purposes only.

#### References

rkf54

Runge-Kutta-Fehlberg

## **Description**

Runge-Kutta-Fehlberg with adaptive step size.

# Usage

320 rkf54

## Arguments

f	function in the differential equation $y' = f(x, y)$ .
a, b	endpoints of the interval.
y0	starting values at a.
tol	relative tolerance, used for determining the step size.
control	list for influencing the step size with components hmin, hmax, the minimal, maximal step size jmax, the maximally allowed number of steps.
	additional parameters to be passed to the function.

#### **Details**

Runge-Kutta-Fehlberg is a kind of Runge-Kutta method of solving ordinary differential equations of order (5, 4) with variable step size.

"At each step, two different approximations for the solution are made and compared. If the two answers are in close agreement, the approximation is accepted. If the two answers do not agree to a specified accuracy, the step size is reduced. If the answers agree to more significant digits than required, the step size is increased."

Some textbooks promote the idea to use the five-order formula as the accepted value instead of using it for error estimation. This approach is taken here, that is why the function is called rkf54. The idea is still debated as the accuracy determinations appears to be diminished.

### Value

List with components x for grid points between a and b and y the function values of the numerical solution.

#### Note

This function serves demonstration purposes only.

```

rmserr

Accuracy Measures

### **Description**

Calculates different accuracy measures, most prominently RMSE.

## Usage

```
rmserr(x, y, summary = FALSE)
```

### **Arguments**

x, y two vectors of real numbers summary logical; should a summary be printed to the screen?

...

### **Details**

Calculates six different measures of accuracy for two given vectors or sequences of real numbers:

MAE	Mean Absolute Error
MSE	Mean Squared Error
<b>RMSE</b>	Root Mean Squared Error
MAPE	Mean Absolute Percentage Error
<b>LMSE</b>	Normalized Mean Squared Error
rSTD	relative Standard Deviation

3.6 44 4 . 5

322 romberg

### Value

Returns a list with different accuracy measures.

#### Note

Often used in Data Mining for predicting the accuracy of predictions.

#### References

Gentle, J. E. (2009). Computational Statistics, section 10.3. Springer Science+Business Media LCC, New York.

## **Examples**

```
x <- rep(1, 10)
y <- rnorm(10, 1, 0.1)
rmserr(x, y, summary = TRUE)</pre>
```

romberg

Romberg Integration

### **Description**

Romberg Integration

### Usage

```
romberg(f, a, b, maxit = 25, tol = 1e-12, ...)
```

### **Arguments**

```
f function to be integrated.

a, b end points of the interval.

maxit maximum number of iterations.

tol requested tolerance.

variables to be passed to the function.
```

### **Details**

Simple Romberg integration with an explicit Richardson method applied to a series of trapezoidal integrals. This scheme works best with smooth and non-oscillatory functions and needs the least number of function calls among all integration routines.

The function does *not* need to be vectorized.

# Value

List of value, number or iterations, and relative error.

roots, polyroots 323

## Note

Using a trapezoid formula Romberg integration will use 2\*(2^iter-1)+iter function calls. By remembering function values this could be reduced to 2^iter+1 calls.

### **Examples**

roots, polyroots

Polynomial Roots

## **Description**

Computes the roots (and multiplicities) of a polynomial.

## Usage

```
roots(p)
polyroots(p, ntol = 1e-04, ztol = 1e-08)
rootsmult(p, r, tol=1e-12)
```

## Arguments

```
p vector of real or complex numbers representing the polynomial.
```

r a possible root of the polynomial.

tol, ntol, ztol norm tolerance and accuracy for polyroots.

324 rosser

### **Details**

The function roots computes roots of a polynomial as eigenvalues of the companion matrix.

polyroots attempts to refine the results of roots with special attention to multiple roots. For a reference of this implementation see F. C. Chang, "Solving multiple-root polynomials", IEEE Antennas and Propagation Magazine Vol. 51, No. 6 (2010), pp. 151-155.

rootsmult determines te order of a possible root r. As this computation is problematic in double precision, the result should be taken with a grain of salt.

### Value

roots returns a vector holding the roots of the polynomial, rootsmult the multiplicity of a root as an integer. And polyroots returns a data frame with a column 'root' and a column 'mult' giving the multiplicity of that root.

### See Also

rosser

Rosser Matrix

## **Description**

Generate the Rosser matrix.

# Usage

```
rosser()
```

#### **Details**

This is a classic symmetric eigenvalue test problem. It has a double eigenvalue, three nearly equal eigenvalues, dominant eigenvalues of opposite sign, a zero eigenvalue, and a small, nonzero eigenvalue.

rot90 325

### Value

```
matrix of size 8 x 8
```

#### See Also

```
wilkinson
```

# **Examples**

```
rosser()
```

rot90

Matrix Rotation

# Description

Rotate matrices for 90, 180, or 270 degrees..

### Usage

```
rot90(a, k = 1)
```

## **Arguments**

a numeric or complex matrix

k scalar integer number of times the matrix will be rotated for 90 degrees; may be negative.

### **Details**

Rotates a numeric or complex matrix for 90 (k = 1), 180 (k = 2) or 270 (k = 3 or k = -1) degrees. Value of k is taken mod 4.

# Value

the original matrix rotated

```
a <- matrix(1:12, nrow=3, ncol=4, byrow=TRUE)
rot90(a)
rot90(a, 2)
rot90(a, -1)</pre>
```

326 rref

rref

Reduced Row Echelon Form

### **Description**

Produces the reduced row echelon form of A using Gauss Jordan elimination with partial pivoting.

# Usage

rref(A)

# Arguments

Α

numeric matrix.

### **Details**

A matrix of "row-reduced echelon form" has the following characteristics:

- 1. All zero rows are at the bottom of the matrix
- 2. The leading entry of each nonzero row after the first occurs to the right of the leading entry of the previous row.
- 3. The leading entry in any nonzero row is 1.
- 4. All entries in the column above and below a leading 1 are zero.

Roundoff errors may cause this algorithm to compute a different value for the rank than rank, orth or null.

#### Value

A matrix the same size as m.

### Note

This serves demonstration purposes only; don't use for large matrices.

runge

Runge Function

### **Description**

Runge's test function for interpolation techniques.

### Usage

```
runge(x)
```

### **Arguments**

Χ

numeric scalar.

#### **Details**

Runge's function is a classical test function for interpolation and and approximation techniques, especially for equidistant nodes.

For example, when approximating the Runge function on the interval [-1,1], the error at the endpoints will diverge when the number of nodes is increasing.

### Value

Numerical value of the function.

328 savgol

    p <- polyfit(xp, yp, n[i]-1)
    y <- polyval(p, x)
    lines(x, y, lty=i) }

## End(Not run)</pre>
```

savgol

Savitzky-Golay Smoothing

# Description

Polynomial filtering method of Savitzky and Golay.

### Usage

```
savgol(T, fl, forder = 4, dorder = 0)
```

### **Arguments**

T	Vector of signals to be filtered.
fl	Filter length (for instance $fl = 51151$ ), has to be odd.
forder	Filter order $(2 = quadratic filter, 4 = quartic)$ .
dorder	Derivative order $(0 = \text{smoothing}, 1 = \text{first derivative}, \text{etc.})$ .

#### **Details**

Savitzky-Golay smoothing performs a local polynomial regression on a series of values which are treated as being equally spaced to determine the smoothed value for each point. Methods are also provided for calculating derivatives.

### Value

Vector representing the smoothed time series.

segm\_distance 329

### Note

For derivatives T2 has to be divided by the step size to the order (and to be multiplied by k! — the sign appears to be wrong).

# Author(s)

Peter Riegler implemented a Matlab version in 2001. Based on this, Hans W. Borchers published an R version in 2003.

#### References

See Numerical Recipes, 1992, Chapter 14.8, for details.

#### See Also

```

```

### **Examples**

```
# *** Sinosoid test function ***
ts <- sin(2*pi*(1:1000)/200)
t1 <- ts + rnorm(1000)/10
t2 <- savgol(t1, 51)
## Not run:
plot( 1:1000, t1, col = "grey")
lines(1:1000, ts, col = "blue")
lines(1:1000, t2, col = "red")
## End(Not run)</pre>
```

segm\_distance

Segment Distance

### **Description**

The minimum distance between a point and a segment, or the minimum distance between points of two segments.

### Usage

```
segm_distance(p1, p2, p3, p4 = c())
```

#### **Arguments**

```
p1, p2 end points of the first segment.
```

p3, p4 end points of the second segment, or the point p3 alone if p4 is NULL.

segm\_intersect

#### **Details**

If p4=c(), determines the orthogonal line to the segment through the single point and computes the distance to the intersection point.

Otherwise, it computes the distances of all four end points to the other segment and takes the minimum of those.

#### Value

Returns a list with component 1 the minimum distance and components p,q the two nearest points. If p4=c() then point p lies on the segment and q is p4.

#### Note

The interfaces of segm\_intersect and segm\_distance should be brought into line.

#### See Also

```
segm_intersect
```

### **Examples**

segm\_intersect

Segment Intersection

### **Description**

Do two segments have at least one point in common?

### Usage

```
segm_intersect(s1, s2)
```

segm\_intersect 331

## Arguments

s1, s2 Two segments, represented by their end points; i.e.,  $s \leftarrow p1, p2$  are the end points.

#### **Details**

First compares the 'bounding boxes', and if those intersect looks at whether the other end points lie on different sides of each segment.

#### Value

Logical, TRUE if these segments intersect.

#### Note

Should be written without reference to the cross function. Should also return the intersection point, see the example.

```

332 semilogx,semilogy

semilogx,semilogy

Semi-logarithmic Plots (Matlab Style)

# Description

Generates semi- and double-logarithmic plots.

# Usage

```
semilogx(x, y, ...)
semilogy(x, y, ...)
loglog(x, y, ...)
```

# **Arguments**

. . .

```
x-, y-coordinates.
х, у
                   additional graphical parameters passed to the plot function.
```

# **Details**

Plots data in logarithmic scales for the x-axis or y-axis, or uses logarithmic scales in both axes, and adds grid lines.

### Value

Generates a plot, returns nothing.

#### Note

Matlab's logarithmic plots find a more appropriate grid.

### See Also

```
plot with log= option.
```

```
## Not run:
x \leftarrow logspace(-1, 2)
loglog(x, exp(x), type = 'b')
## End(Not run)
```

shooting 333

# Description

The shooting method solves the boundary value problem for second-order differential equations.

### Usage

```
shooting(f, t0, tfinal, y0, h, a, b,
    itermax = 20, tol = 1e-6, hmax = 0)
```

#### **Arguments**

f	function in the differential equation $y'' = f(x, y, y')$ .
t0, tfinal	start and end points of the interval.
y0	starting value of the solution.
h	function defining the boundary condition as a function at the end point of the interval.
a, b	two guesses of the derivative at the start point.
itermax	maximum number of iterations for the secant method.
tol	tolerance to be used for stopping and in the ode45 solver.
hmax	maximal step size, to be passed to the solver.

### **Details**

A second-order differential equation is solved with boundary conditions y(t0) = y0 at the start point of the interval, and h(y(tfinal), dy/dt(tfinal)) = 0 at the end. The zero of h is found by a simple secant approach.

### Value

Returns a list with two components, t for grid (or 'time') points between t0 and tfinal, and y the solution of the differential equation evaluated at these points.

#### Note

Replacing secant with Newton's method would be an easy exercise. The same for replacing ode45 with some other solver.

```

shubert

Shubert-Piyavskii Method

### **Description**

Shubert-Piyavskii Univariate Function Maximization

#### Usage

```
shubert(f, a, b, L, crit = 1e-04, nmax = 1000)
```

# Arguments

f	function to be optimized.
a, b	search between a and b for a maximum.
L	a Lipschitz constant for the function.
crit	critical value
nmax	maximum number of steps.

shubert 335

### **Details**

The Shubert-Piyavskii method, often called the Sawtooth Method, finds the global maximum of a univariate function on a known interval. It is guaranteed to find the global maximum on the interval under certain conditions:

The function f is Lipschitz-continuous, that is there is a constant L such that

$$|f(x) - f(y)| \le L|x - y|$$

for all x, y in [a, b].

The process is stopped when the improvement in the last step is smaller than the input argument crit.

#### Value

Returns a list with the following components:

xopt the x-coordinate of the minimum found.

fopt the function value at the minimum.

nopt number of steps.

336 Si, Ci

Si, Ci

Sine and Cosine Integral Functions

#### **Description**

Computes the sine and cosine integrals through approximations.

### Usage

Si(x)

Ci(x)

### **Arguments**

Х

Scalar or vector of real numbers.

#### **Details**

The sine and cosine integrals are defined as

$$Si(x) = \int_0^x \frac{\sin(t)}{t} dt$$

$$Ci(x) = -\int_{x}^{\infty} \frac{\cos(t)}{t} dt = \gamma + \log(x) + \int_{0}^{x} \frac{\cos(t) - 1}{t} dt$$

where  $\gamma$  is the Euler-Mascheroni constant.

### Value

Returns a scalar of sine resp. cosine integrals applied to each element of the scalar/vector. The value Ci(x) is not correct, it should be Ci(x)+pi\*i, only the real part is returned!

The function is not truely vectorized, for vectors the values are calculated in a for-loop. The accuracy is about 10^-13 and better in a reasonable range of input values.

#### See Also

sinc, expint

sigmoid 337

#### **Examples**

sigmoid

Sigmoid Function

# Description

Sigmoid function (aka sigmoidal curve or logistic function).

### Usage

```
sigmoid(x, a = 1, b = 0)
logit(x, a = 1, b = 0)
```

# Arguments

x numeric vector.

a, b parameters.

### **Details**

The sigmoidal function with parameters a, b is the function

$$y = 1/(1 + e^{-a(x-b)})$$

The sigmoid function is also the solution of the ordinary differential equation

$$y' = y(1 - y)$$

with y(0) = 1/2 and has an indefinite integral  $\ln(1 + e^x)$ .

The logit function is the inverse of the sigmoid function and is (therefore) omly defined between 0 and 1. Its definition is

$$y = b + 1/alog(x/(1-x))$$

338 simpadpt

#### Value

Numeric/complex scalar or vector.

### **Examples**

simpadpt

Adaptive Simpson Quadrature

### **Description**

Numerically evaluate an integral using adaptive Simpson's rule.

# Usage

```
simpadpt(f, a, b, tol = 1e-6, ...)
```

#### **Arguments**

f univariate function, the integrand.

a, b lower limits of integration; must be finite.

tol relative tolerance

... additional arguments to be passed to f.

#### **Details**

Approximates the integral of the function f from a to b to within an error of tol using recursive adaptive Simpson quadrature.

#### Value

A numerical value or vector, the computed integral.

simpson2d 339

### Note

Based on code from the book by Quarteroni et al., with some tricks borrowed from Matlab and Octave.

#### References

Quarteroni, A., R. Sacco, and F. Saleri (2007). Numerical Mathematics. Second Edition, Springer-Verlag, Berlin Heidelberg.

xs \leftarrow seq(-5, 1, length.out = N)
ys <- numeric(N)
for (i in 1:N) ys[i] <- dilog(xs[i])</pre>
plot(xs, ys, type = "1", col = "blue",
             main = "Dilogarithm function")
grid()
## End(Not run)
```

simpson2d

Double Simpson Integration

### **Description**

Numerically evaluate double integral by 2-dimensional Simpson method.

# Usage

```
simpson2d(f, xa, xb, ya, yb, nx = 128, ny = 128, ...)
```

340 sind,cosd,tand, etc.

## **Arguments**

f	function of two variables, the integrand.
xa, xb	left and right endpoint for first variable.
ya, yb	left and right endpoint for second variable.
nx, ny	number of intervals in x- and y-direction.
	additional parameters to be passed to the integrand.

### **Details**

The 2D Simpson integrator has weights that are most easily determined by taking the outer product of the vector of weights for the 1D Simpson rule.

#### Value

Numerical scalar, the value of the integral.

simpson2d(f3, -1, 1, -1, 1) # 2.094393912 , i.e. 2/3*pi , err = 1e-6
```

```
sind, cosd, tand, etc. Trigonometric Functions in Degrees
```

### **Description**

Trigonometric functions expecting input in degrees, not radians.

sind,cosd,tand, etc. 341

## Usage

```
sind(x)
cosd(x)
tand(x)
cotd(x)
asind(x)
acosd(x)
atand(x)
acotd(x)
secd(x)
cscd(x)
asecd(x)
atan2d(x1, x2)
```

### **Arguments**

x, x1, x2 numeric or complex scalars or vectors

#### **Details**

The usual trigonometric functions with input values as scalar or vector in degrees. Note that tan(x) with fractional part does not return NaN as tanpi(x), but is computed as sind(x)/cosd(x).

For atan2d the inputs x1, x2 can be both degrees or radians, but don't mix! The result is in degrees, of course.

#### Value

Returns a scalar or vector of numeric values.

#### Note

These function names are available in Matlab, that is the reason they have been added to the 'pracma' package.

#### See Also

Other trigonometric functions in R.

```
# sind(x) and cosd(x) are accurate for x which are multiples # of 90 and 180 degrees, while tand(x) is problematic. 

x <- seq(0, 720, by = 90)
sind(x) # 0 1 0 -1 0 1 0 -1 0 0 
cosd(x) # 1 0 -1 0 1 0 -1 0 1 
tand(x) # 0 Inf 0 -Inf 0 Inf 0 -Inf 0 
tand(x) # Inf 0 -Inf 0 Inf 0 -Inf 0 Inf
```

342 size

```
x \leftarrow seq(5, 85, by = 20)

asind(sind(x))  # 5 25 45 65 85

asecd(sec(x))

tand(x)  # 0.08748866 0.46630766 1.00000000 ...

atan2d(1, 1)  # 45
```

size

Size of Matrix

### **Description**

Provides the dimensions of x.

# Usage

```
size(x, k)
```

### **Arguments**

x vector, matrix, or array

k integer specifying a particular dimension

### **Details**

Returns the number of dimensions as length(x).

Vector will be treated as a single row matrix.

#### Value

vector containing the dimensions of x, or the k-th dimension if k is not missing.

### Note

The result will differ from Matlab when x is a character vector.

# See Also

dim

```
size(1:8)
size(matrix(1:8, 2, 4)) # 2 4
size(matrix(1:8, 2, 4), 2) # 4
size(matrix(1:8, 2, 4), 3) # 1
```

softline 343

softline	Soft (Inexact) Line Search	

# Description

Fletcher's inexact line search algorithm.

# Usage

```
softline(x0, d0, f, g = NULL)
```

# Arguments

x0	initial point for linesearch.
d0	search direction from x0.
f	real function of several variables that is to be minimized.
g	gradient of objective function f; computed numerically if not provided.

#### **Details**

Many optimization methods have been found to be quite tolerant to line search imprecision, therefore inexact line searches are often used in these methods.

### Value

Returns the suggested inexact optimization paramater as a real number a0 such that x0+a0\*d0 should be a reasonable approximation.

### Note

Matlab version of an inexact linesearch algorithm by A. Antoniou and W.-S. Lu in their textbook "Practical Optimization". Translated to R by Hans W Borchers.

sorting

Sorting Routines

# **Description**

R implementations of several sorting routines. These implementations are meant for demonstration and lecturing purposes.

#### Usage

```
is.sorted(a)
testSort(n = 1000)

bubbleSort(a)
insertionSort(a)
selectionSort(a)
shellSort(a, f = 2.3)
heapSort(a)
mergeSort(a, m = 10)
mergeOrdered(a, b)
quickSort(a, m = 3)
quickSortx(a, m = 25)
```

#### **Arguments**

n

a, b Numeric vectors to be sorted or merged.
 f Retracting factor for shellSort.
 m Size of subsets that are sorted by insertionSort when the sorting procedure is called recursively.

Only in testSort: the length of a vector of random numbers to be sorted.

sorting 345

#### **Details**

bubbleSort(a) is the well-known "bubble sort" routine; it is forbiddingly slow.

insertionSort(a) sorts the array one entry at a time; it is slow, but quite efficient for small data sets.

selectionSort(a) is an in-place sorting routine that is inefficient, but noted for its simplicity.

shellSort(a, f = 2.3) exploits the fact that insertion sort works efficiently on input that is already almost sorted. It reduces the gaps by the factor f; f=2.3 is said to be a reasonable choice.

heapSort(a) is not yet implemented.

mergeSort(a,m = 10) works recursively, merging already sorted parts with mergeOrdered. m should be between 3 and 1/1000 of the size of a.

mergeOrdered(a,b) works only correctly if a and a are already sorted.

quickSort(a,m=3) realizes the celebrated "quicksort algorithm" and is the fastest of all implementations here. To avoid too deeply nested recursion with R, insertionSort is called when the size of a subset is smaller than m.

Values between 3..30 seem reasonable and smaller values are better, with the risk of running into a too deeply nested recursion.

quickSort(a,m = 25) is an extended version where the split is calculated more carefully, but in general this approach takes too much time.

Values for m are 20..40 with m=25 favoured.

testSort(n = 1000) is a test routine, e.g. for testing your computer power. On an iMac, quickSort will sort an array of size 1,000,000 in less than 15 secs.

#### Value

All routines return the vector sorted.

is. sorted indicates logically whether the vector is sorted.

### Note

At the moment, only increasingly sorting is possible (if needed apply rev afterwards).

system.time(y <- mergeOrdered(a, b))
is.sorted(y)
## End(Not run)</pre>
```

sortrows

Sort Rows of a Matrix (Matlab Style)

# Description

Sort rows of a matrix according to values in a column.

# Usage

```
sortrows(A, k = 1)
```

# Arguments

A numeric matrix.

k number of column to sort the matrix accordingly.

# **Details**

sortrows (A,k) sorts the rows of the matrix A such that column k is increasingly sorted.

# Value

Returns the sorted matrix.

### See Also

sort

```
A <- magic(5)
sortrows(A)
sortrows(A, k = 2)
```

spinterp 347

spinterp

Monotone (Shape-Preserving) Interpolation

### **Description**

Monotone interpolation preserves the monotonicity of the data being interpolated, and when the data points are also monotonic, the slopes of the interpolant should also be monotonic.

#### Usage

```
spinterp(x, y, xp)
```

### **Arguments**

x, y x- and y-coordinates of the points that shall be interpolated.

xp points that should be interpolated.

#### **Details**

This implementation follows a cubic version of the method of Delbourgo and Gregory. It yields 'shaplier' curves than the Stineman method.

The calculation of the slopes is according to recommended practice:

- monotonic and convex -> harmonic
- monotonic and nonconvex -> geometric
- nonmonotonic and convex -> arithmetic
- nonmonotonic and nonconvex -> circles (Stineman) [not implemented]

The choice of supplementary coefficients r[i] depends on whether the data are montonic or convex or both:

- monotonic, but not convex
- otherwise

and that can be detected from the data. The choice r[i]=3 for all i results in the standard cubic Hermitean rational interpolation.

### Value

The interpolated values at all the points of xp.

#### Note

At the moment, the data need to be monotonic and the case of convexity is not considered.

sgrtm, rootm

Matrix Square and p-th Roots

### **Description**

Computes the matrix square root and matrix p-th root of a nonsingular real matrix.

## Usage

```
sqrtm(A, kmax = 20, tol = .Machine$double.eps^(1/2))
signm(A, kmax = 20, tol = .Machine$double.eps^(1/2))
rootm(A, p, kmax = 20, tol = .Machine$double.eps^(1/2))
```

#### **Arguments**

A numeric, i.e. real, matrix.

p p-th root to be taken.

kmax maximum number of iterations.

tol

**Details** 

A real matrix may or may not have a real square root; if it has no real negative eigenvalues. The number of square roots can vary from two to infinity. A positive definite matric has one distinguished square root, called the principal one, with the property that the eigenvalues lie in the segment  $\{z \mid -pi/p < arg(z) < pi/p\}$  (for the p-th root).

absolut tolerance, norm distance of A and B^p.

The matrix square root sqrtm(A) is computed here through the Denman-Beavers iteration (see the references) with quadratic rate of convergence, a refinement of the common Newton iteration determining roots of a quadratic equation.

The matrix p-th root rootm(A) is computed as a complex integral

$$A^{1/p} = \frac{p\sin(\pi/p)}{\pi} A \int_0^\infty (x^p I + A)^{-1} dx$$

applying the trapezoidal rule along the unit circle.

One application is the computation of the matrix logarithm as

$$\log A = 2^k \log A^{1/2^k}$$

350 sqrtm,rootm

such that the argument to the logarithm is close to the identity matrix and the Pade approximation can be applied to  $\log(I + X)$ .

The matrix sector function is defined as  $sectm(A,m)=(A^m)^{-1/p}%*%A$ ; for p=2 this is the matrix sign function.

```
S=signm(A) is real if A is and has the following properties:
```

```
S^2=Id; SA=AS
```

```
singm([0 A; B 0])=[0 C; C^{-1} 0] where C=A(BA)^{-1}
```

These functions arise in control theory.

#### Value

sqrtm(A) returns a list with components

B square root matrix of A.

Binv inverse of the square root matrix.

k number of iterations.

acc accuracy or absolute error.

rootm(A) returns a list with components

B square root matrix of A.k number of iterations.

acc accuracy or absolute error.

If k is negative the iteration has not converged.

signm just returns one matrix, even when there was no convergence.

### Note

The p-th root of a positive definite matrix can also be computed from its eigenvalues as

```
E <-eigen(A)
```

V <-E\\$vectors; U <-solve(V)</pre>

D <-diag(E\\$values)</pre>

B <-V %\*% D^(1/p) %\*% U

or by applying the functions expm, logm in package 'expm':

```
B < -expm(1/p * logm(A))
```

As these approaches all calculate the principal branch, the results are identical (but will numerically slightly differ).

squareform

Format Distance Matrix (Matlab Style)

## **Description**

Format or generate a distance matrix.

# Usage

```
squareform(x)
```

#### **Arguments**

x numeric vector or matrix.

352 std

### **Details**

If x is a vector as created by the dist function, it converts it into a fulll square, symmetric matrix. And if x is a distance matrix, i.e. square, symmetric amd with zero diagonal elements, it returns the flattened lower triangular submatrix.

#### Value

Returns a matrix if x is a vector, and a vextor if x is a matrix.

### See Also

```
dist
```

# **Examples**

```
x <- 1:6
y <- squareform(x)
# 0 1 2 3
# 1 0 4 5
# 2 4 0 6
# 3 5 6 0
all(squareform(y) == x)
# TRUE</pre>
```

std

Standard Deviation (Matlab Style)

### **Description**

Standard deviation of the values of x.

#### Usage

```
std(x, flag=0)
```

# Arguments

x numeric vector or matrix

flag numeric scalar. If 0, selects unbiased algorithm; and if 1, selects the biased version.

### **Details**

If flag = 0 the result is the square root of an unbiased estimator of the variance. std(X,1) returns the standard deviation producing the second moment of the set of values about their mean.

std\_err 353

### Value

Return value depends on argument x. If vector, returns the standard deviation. If matrix, returns vector containing the standard deviation of each column.

### Note

flag = 0 produces the same result as R's sd().

# **Examples**

```
std(1:10) # 3.027650
std(1:10, flag=1) # 2.872281
```

std\_err

Standard Error

# **Description**

Standard error of the values of x.

### Usage

```
std_err(x)
```

# Arguments

Х

numeric vector or matrix

#### **Details**

Standard error is computed as var(x)/length(x).

#### Value

Returns the standard error of all elements of the vector or matrix.

```
std_err(1:10) #=> 0.9574271
```

354 steep\_descent

|--|

### **Description**

Function minimization by steepest descent.

### Usage

# Arguments

	.44 .1 .
x0	start value.

f function to be minimized.

g gradient function of f; if NULL, a numerical gradient will be calculated.

info logical; shall information be printed on every iteration?

maxiter max. number of iterations.

tol relative tolerance, to be used as stopping rule.

### **Details**

Steepest descent is a line search method that moves along the downhill direction.

#### Value

List with following components:

xmin minimum solution found. fmin value of f at minimum.

niter number of iterations performed.

### Note

Used some Matlab code as described in the book "Applied Numerical Analysis Using Matlab" by L. V.Fausett.

```

str2num

Converting string to number (Matlab style)

#### **Description**

Functions for converting strings to numbers and numbers to strings.

#### Usage

```
str2num(S)
num2str(A, fmt = 3)
```

### Arguments

S string containing numbers (in Matlab format).

A numerical vector or matrix.

fmt format string, or integer indicating number of decimals.

#### **Details**

str2num converts a string containing numbers into a numerical object. The string can begin and end with '[' and ']', numbers can be separated with blanks or commas; a semicolon within the brackets indicates a new row for matrix input. When a semicolon appears behind the braces, no output is shown on the command line.

num2str converts a numerical object, vector or matrix, into a character object of the same size. fmt will be a format string for use in sprintf, or an integer n being used in '%.nf'.

356 streat

### Value

Returns a vector or matrix of the same size, converted to strings, respectively numbers.

#### See Also

```
sprintf
```

# **Examples**

```
str1 <- " [1 2 3; 4, 5, 6; 7,8,9] "
str2num(str1)
# matrix(1:9, nrow = 3, ncol = 3, byrow = TRUE)

# str2 <- " [1 2 3; 45, 6; 7,8,9] "
# str2num(str2)
# Error in str2num(str2) :
# All rows in Argument 's' must have the same length.

A <- matrix(c(pi, 0, exp(1), 1), 2, 2)
B <- num2str(A, 2); b <- dim(B)
B <- as.numeric(B); dim(B) <- b
B
# [,1] [,2]
# [1,] 3.14 2.72
# [2,] 0.00 1.00</pre>
```

strcat

String Concatenation

### **Description**

Concatenate all strings in a character vector

#### **Usage**

```
strcat(s1, s2 = NULL, collapse = "")
```

# **Arguments**

```
s1 character string or vectors
s2 character string or vector, or NULL (default)
collapse character vector of length 1 (at best a single character)
```

#### **Details**

Concatenate all strings in character vector s1, if s2 is NULL, or cross-concatenate all string elements in s1 and s2 using collapse as 'glue'.

strcmp 357

### Value

a character string or character vector

#### See Also

paste

# **Examples**

```
strcat(c("a", "b", "c")) #=> "abc"
strcat(c("a", "b"), c("1", "2"), collapse="x") #=> "ax1" "ax2" "bx1" "bx2"
```

strcmp

String Comparison

### **Description**

Compare two strings or character vectors for equality.

# Usage

```
strcmp(s1, s2)
strcmpi(s1, s2)
```

# Arguments

s1, s2

character strings or vectors

### **Details**

For strcmp comparisons are case-sensitive, while for strcmpi the are case-insensitive. Leading and trailing blanks do count.

#### Value

logical, i.e. TRUE if s1 and s2 have the same length as character vectors and all elements are equal as character strings, else FALSE.

# See Also

strcat

```
strcmp(c("yes", "no"), c("yes", "no"))
strcmpi(c("yes", "no"), c("Yes", "No"))
```

358 strfind

strfind

Find Substrings

### **Description**

Find substrings within strings of a character vector.

### Usage

```
strfind(s1, s2, overlap = TRUE)
strfindi(s1, s2, overlap = TRUE)
findstr(s1, s2, overlap = TRUE)
```

# **Arguments**

s1 character string or character vector s2 character string (character vector of length 1) overlap logical (are overlapping substrings allowed)

#### **Details**

strfind finds positions of substrings within s1 that match exactly with s2, and is case sensitive; no regular patterns.

strfindi does not distinguish between lower and upper case.

findstr should only be used as internal function, in Matlab it is deprecated. It searches for the shorter string within the longer one.

### Value

Returns a vector of indices, or a list of such index vectors if s2 is a character vector of length greater than 1.

#### See Also

```
\operatorname{strcmp}
```

```
S <- c("", "ab", "aba", "aba aba", "abababa")
s <- "aba"
strfind(S, s)
strfindi(toupper(S), s)
strfind(S, s, overlap = FALSE)</pre>
```

strjust 359

strjust

Justify character vector

# Description

Justify the strings in a character vector.

### Usage

```
strjust(s, justify = c("left", "right", "center"))
```

### **Arguments**

s Character vector.

justify Whether to justify left, right, or centered.

#### **Details**

strjust(s) or strjust(s,justify = ``right'') returns a right-justified character vector. All strings have the same length, the length of the longest string in s — but the strings in s have been trimmed before.

```
strjust(s, justify = ``left'') does the same, with all strings left-justified.
```

strjust(s, justify = ``centered'') returns all string in s centered. If an odd number of blanks has to be added, one blank more is added to the left than to the right.

### Value

A character vector of the same length.

# See Also

```
\operatorname{strTrim}
```

```
S <- c("abc", "letters", "1", "2 2")
strjust(S, "left")</pre>
```

360 strRep

Find and replace substring

### **Description**

Find and replace all occurrences of a substring with another one in all strings of a character vector.

# Usage

```
strRep(s, old, new)
```

### **Arguments**

s Character vector.

old String to be replaced.

new String that replaces another one.

### **Details**

Replaces all occurrences of old with new in all strings of character vector s. The matching is case sensitive.

#### Value

A character vector of the same length.

#### See Also

```
gsub, regexprep
```

strTrim 361

strTrim

Remove leading and trailing white space.

## **Description**

Removes leading and trailing white space from a string.

## Usage

```
strTrim(s)
deblank(s)
```

# Arguments

S

character string or character vector

#### **Details**

strTrim removes leading and trailing white space from a string or from all strings in a character vector.

deblank removes trailing white space only from a string or from all strings in a character vector.

## Value

A character string or character vector with (leading and) trailing white space.

#### See Also

```
strjust
```

```
s <- c(" abc", "abc ", " abc ", " a b c ", "abc", "a b c")
strTrim(s)
deblank(s)</pre>
```

362 subspace

subspace

Angle between two subspaces

## Description

Finds the angle between two subspaces.

#### Usage

```
subspace(A, B)
```

## Arguments

A, B

Numeric matrices; vectors will be considered as column vectors. These matrices must have the same number or rows.

#### **Details**

Finds the angle between two subspaces specified by the columns of A and B.

#### Value

An angle in radians.

#### Note

It is not necessary that two subspaces be the same size in order to find the angle between them. Geometrically, this is the angle between two hyperplanes embedded in a higher dimensional space.

#### References

Strang, G. (1998). Introduction to Linear Algebra. Wellesley-Cambridge Press.

H <- hadamard(8)
A <- H[, 2:4]
B <- H[, 5:8]
subspace(A, B) #=> 1.5708 or pi/2, i.e. A and B are orthogonal
```

sumalt 363

sumalt

Alternating Series Acceleration

## **Description**

Computes the value of an (infinite) alternating sum applying an acceleration method found by Cohen et al.

#### Usage

```
sumalt(f_alt, n)
```

#### **Arguments**

f\_alt a funktion of k=0.. Inf that returns element a\_k of the infinite alternating series.n number of elements of the series used for calculating.

#### **Details**

Computes the sum of an alternating series (whose entries are strictly decreasing), applying the acceleration method developed by H. Cohen, F. Rodriguez Villegas, and Don Zagier.

For example, to compute the Leibniz series (see below) to 15 digits exactly, 10^15 summands of the series will be needed. This acceleration approach here will only need about 20 of them!

## Value

Returns an approximation of the series value.

# Author(s)

Implemented by Hans W Borchers.

#### **Examples**

```
# Beispiel: Leibniz-Reihe 1 - 1/3 + 1/5 - 1/7 +- ...
a_pi4 \leftarrow function(k) (-1)^k / (2*k + 1)
sumalt(a_pi4, 20) # 0.7853981633974484 = pi/4 + eps()
# Beispiel: Van Wijngaarden transform needs 60 terms
n <- 60; N <- 0:n
a <- cumsum((-1)^N / (2*N+1))
for (i in 1:n) {
   a \leftarrow (a[1:(n-i+1)] + a[2:(n-i+2)]) / 2
a - pi/4 # 0.7853981633974483
# Beispiel: 1 - 1/2^2 + 1/3^2 - 1/4^2 + ...
b_alt <- function(k) (-1)^k / (k+1)^2
sumalt(b_alt, 20) # 0.8224670334241133 = pi^2/12 + eps()
## Not run:
# Dirichlet eta() function: eta(s) = 1/1^s - 1/2^s + 1/3^s -+ ...
  eta_ <- function(s) {
   eta_alt <- function(k) (-1)^k / (k+1)^s
   sumalt(eta_alt, 30)
  }
                                # 0.6931471805599453 = log(2)
  eta_(1)
  abs(eta_(1+1i) - eta(1+1i)) # 1.24e-16
## End(Not run)
```

taylor

Taylor Series Approximation

#### **Description**

Local polynomial approximation through Taylor series.

## Usage

```
taylor(f, x0, n = 4, ...)
```

## **Arguments**

f differentiable function.

x0 point where the series expansion will take place.

n Taylor series order to be used; should be n <= 8.

... more variables to be passed to function f.

tic,toc 365

#### **Details**

Calculates the first four coefficients of the Taylor series through numerical differentiation and uses some polynomial 'yoga'.

## Value

Vector of length n+1 representing a polynomial of degree n.

#### Note

TODO: Pade approximation.

## See Also

fderiv

## **Examples**

tic,toc

MATLAB timer functions

## **Description**

Provides stopwatch timer. Function tic starts the timer and toc updates the elapsed time since the timer was started.

#### Usage

```
tic(gcFirst=FALSE)
toc(echo=TRUE)
```

366 titanium

#### **Arguments**

gcFirst	logical scalar. If TRUE, perform garbage collection prior to starting stopwatch
echo	logical scalar. If TRUE, print elapsed time to screen

#### **Details**

Provides analog to system. time. Function toc can be invoked multiple times in a row.

#### Value

toc invisibly returns the elapsed time as a named scalar (vector).

#### Author(s)

P. Roebuck openced

# **Examples**

```
tic()
for(i in 1:100) mad(runif(1000)) # kill time
toc()
```

titanium

Titanium Test Data

# Description

The Titanium data set describes measurements of a certain property of titanium as a function of temperature.

#### Usage

```
data(titanium)
```

## **Format**

The format is:

Two columns called 'x' and 'y', the first being the temperature.

#### **Details**

These data have become a standard test for data fitting since they are hard to fit by classical techniques and have a significant amount of noise.

#### **Source**

Boor, C. de, and J. R. Rice (1968). Least squares cubic spline approximation II – Variable knots, CSD TR 21, Comp.Sci., Purdue Univ.

Toeplitz 367

## **Examples**

```
## Not run:
data(titanium)
plot(titanium)
grid()
## End(Not run)
```

Toeplitz

Toeplitz Matrix

## **Description**

Generate Toeplitz matrix from column and row vector.

## Usage

```
Toeplitz(a, b)
```

# Arguments

a vector that will be the first column

b vector that if present will form the first row.

## **Details**

Toeplitz(a,b) returns a (non-symmetric) Toeplitz matrix whose first column is a and whose first row is b. The following rows are shifted to the left.

If the first element of b differs from the last element of a it is overwritten by this one (and a warning sent).

## Value

```
Matrix of size (length(a), length(b)).
```

## Note

stats::Toeplitz does not allow to specify the row vector, that is returns only the *symmetric* Toeplitz matrix.

#### See Also

hankel

```
Toeplitz(c(1, 2, 3, 4, 5))
Toeplitz(c(1, 2, 3, 4, 5), c(1.5, 2.5, 3.5, 4.5, 5.5))
```

368 trapz

Trace

Matrix trace

## **Description**

Sum of the main diagonal elements.

## Usage

```
Trace(a)
```

## **Arguments**

а

a square matrix

## **Details**

Sums the elements of the main diagonal of areal or complrx square matrix.

## Value

scalar value

## Note

The corresponding function in Matlab/Octave is called trace(), but this in R has a different meaning.

# See Also

```
Diag, diag
```

## **Examples**

```
Trace(matrix(1:16, nrow=4, ncol=4))
```

trapz

Trapezoidal Integration

# Description

Compute the area of a function with values y at the points x.

# Usage

```
trapz(x, y)
cumtrapz(x, y)
trapzfun(f, a, b, maxit = 25, tol = 1e-07, ...)
```

trapz 369

#### Arguments

X	x-coordinates of points on the x-axis
у	y-coordinates of function values
f	function to be integrated.
a, b	lower and upper border of the integration domain.
maxit	maximum number of steps.
tol	tolerance; stops when improvements are smaller.
	arguments passed to the function.

#### **Details**

The points (x,0) and (x,y) are taken as vertices of a polygon and the area is computed using polyarea. This approach matches exactly the approximation for integrating the function using the trapezoidal rule with basepoints x.

cumtrapz computes the cumulative integral of y with respect to x using trapezoidal integration. x and y must be vectors of the same length, or x must be a vector and y a matrix whose first dimension is length(x).

Inputs x and y can be complex.

trapzfun realizes trapezoidal integration and stops when the difference from one step to the next is smaller than tolerance (or the of iterations get too big). The function will only be evaluated once on each node.

#### Value

Approximated integral of the function, discretized through the points x, y, from min(x) to max(x). Or a matrix of the same size as y.

trapzfun returns a lst with components value the value of the integral, iter the number of iterations, and rel.err the relative error.

#### See Also

```

```
# Calculate the area under the sine curve from 0 to pi:
n <- 101
x <- seq(0, pi, len = n)
y <- sin(x)
trapz(x, y)  #=> 1.999835504

# Use a correction term at the boundary: -h^2/12*(f'(b)-f'(a))
h <- x[2] - x[1]
ca <- (y[2]-y[1]) / h
cb <- (y[n]-y[n-1]) / h
trapz(x, y) - h^2/12 * (cb - ca) #=> 1.999999969
```

370 tri

```
# Use two complex inputs
z <- exp(1i*pi*(0:100)/100)
ct <- cumtrapz(z, 1/z)
ct[[101]  #=> 0+3.14107591i

f <- function(x) x^(3/2)  #
trapzfun(f, 0, 1)  #=> 0.4 with 11 iterations
```

tri

Triangular Matrices (Matlab Style)

#### **Description**

Extract lower or upper triangular part of a matrix.

## Usage

```
tril(M, k = 0)

triu(M, k = 0)
```

# Arguments

M numeric matrix.

k integer, indicating a secondary diagonal.

#### **Details**

tril

Returns the elements on and below the kth diagonal of X, where k = 0 is the main diagonal, k > 0 is above the main diagonal, and k < 0 is below the main diagonal.

triu

Returns the elements on and above the kth diagonal of X, where k = 0 is the main diagonal, k > 0 is above the main diagonal, and k < 0 is below the main diagonal.

#### Value

Matrix the same size as the input matrix.

## Note

For k==0 it is simply an application of the R functions lower.tri resp. upper.tri.

#### See Also

Diag

trigApprox 371

# **Examples**

```
tril(ones(4,4), +1)
# 1 1 0 0
# 1 1 1 0
# 1 1 1 1
# 1 1 1 1

triu(ones(4,4), -1)
# 1 1 1 1
# 0 1 1 1
# 0 0 1 1
```

trigApprox

Trigonometric Approximation

# Description

Computes the trigonometric series.

## Usage

```
trigApprox(t, x, m)
```

# Arguments

t vector of points at which to compute the values of the trigonometric approximation.

x data from t=0 to t=2\*(n-1)\*pi/n.

m degree of trigonometric regression.

## **Details**

Calls trigPoly to get the trigonometric coefficients and then sums the finite series.

## Value

Vector of values the same length as t.

## Note

TODO: Return an approximating function instead.

## See Also

```
trigPoly
```

372 trigPoly

#### **Examples**

```
## Not run:
## Example: Gauss' Pallas data (1801)

dec <- c(408, 89, -66, 10, 338, 807, 1238, 1511, 1583, 1462, 1183, 804)
plot(2*pi*asc/360, dec, pch = "+", col = "red", xlim = c(0, 2*pi), ylim = c(-500, 2000),
     xlab = "Ascension [radians]", ylab = "Declination [minutes]",
     main = "Gauss' Pallas Data")
grid()
points(2*pi*asc/360, dec, pch = "o", col = "red")
ts <- seq(0, 2*pi, len = 100)
xs <- trigApprox(ts ,dec, 1)</pre>
lines(ts, xs, col = "black")
xs <- trigApprox(ts ,dec, 2)</pre>
lines(ts, xs, col = "blue")
legend(3, 0, c("Trig. Regression of degree 1", "Trig. Regression of degree 2",
                  "Astronomical position"), col = c("black", "blue", "red"),
                lty = c(1,1,0), pch = c("", "", "+"))
## End(Not run)
```

trigPoly

Trigonometric Polynomial

## **Description**

Computes the trigonometric coefficients.

#### Usage

```
trigPoly(x, m)
```

#### **Arguments**

```
x data from t=0 to t=2*(n-1)*pi/n.

m degree of trigonometric regression.
```

#### **Details**

Compute the coefficients of the trigonometric series of degree m,

$$a_0 + \sum_k (a_k \cos(kt) + b_k \sin(kt))$$

by applying orthogonality relations.

## Value

Coefficients as a list with components a0, a, and b.

triquad 373

#### Note

For irregular spaced data or data not covering the whole period, use standard regression techniques, see examples.

lines(ts, xs, col="blue")
grid()
## End(Not run)
```

triquad

Gaussian Triangle Quadrature

#### Description

Numerically integrates a function over an arbitrary triangular domain by computing the Gauss nodes and weights.

## Usage

```
triquad(f, x, y, n = 10, tol = 1e-10, ...)
```

374 triquad

# Arguments

f	the integrand as function of two variables.
x	x-coordinates of the three vertices of the triangle.
У	y-coordinates of the three vertices of the triangle.
n	number of nodes.
tol	relative tolerance to be achieved.
	additional parameters to be passed to the function.

#### **Details**

Computes the N<sup>2</sup> nodes and weights for a triangle with vertices given by 3x2 vector. The nodes are produced by collapsing the square to a triangle.

Then f will be applied to the nodes and the result multiplied left and right with the weights (i.e., Gaussian quadrature).

By default, the function applies Gaussian quadrature with number of nodes n=10,21,43,87,175 until the relative error is smaller than the tolerance.

#### Value

The integral as a scalar.

#### Note

A small relative tolerance is *not* really indicating a small absolute tolerance.

#### Author(s)

Copyright (c) 2005 Greg von Winckel Matlab code based on the publication mentioned and available from MatlabCentral (calculates nodes and weights). Translated to R (with permission) by Hans W Borchers.

trisolve 375

trisolve

Tridiagonal Linear System Solver

#### **Description**

Solves tridiagonal linear systems A\*x=rhs efficiently.

# Usage

```
trisolve(a, b, d, rhs)
```

#### **Arguments**

a diagonal of the tridiagonal matrix A.
 b, d upper and lower secondary diagonal of A.
 rhs right hand side of the linear system A\*x=rhs.

#### **Details**

Solves tridiagonal linear systems A\*x=rhs by applying Givens transformations.

By only storing the three diagonals, trisolve has memory requirements of 3\*n instead of n^2 and is faster than the standard solve function for larger matrices.

#### Value

Returns the solution of the tridiagonal linear system as vector.

#### Note

Has applications for spline approximations and for solving boundary value problems (ordinary differential equations).

```

vander

Vandermonde matrix

## **Description**

Generate Vandermonde matrix from a numeric vector.

# Usage

```
vander(x)
```

# Arguments

Numeric vector

# **Details**

Generates the usual Vandermonde matrix from a numeric vector, e.g. applied when fitting a polynomial to given points. Complex values are allowed.

#### Value

Vandermonde matrix of dimension n where n = length(x).

```
vander(c(1:10))
```

vectorfield 377

vectorfield

Vector Field Plotting

# Description

Plotting a vector field

## Usage

## **Arguments**

fun	function of two variables — must be vectorized.
xlim	range of x values.
ylim	range of y values.
n	grid size, proposed 16 in each direction.
scale	scales the length of the arrows.
col	arrow color, proposed 'green'.
	more options presented to the arrows primitive.

## **Details**

Plots a vector field for a function f. Main usage could be to plot the solution of a differential equation into the same graph.

#### Value

Opens a graph window and plots the vector field.

## See Also

```
quiver, arrows
```

```
f <- function(x, y) x^2 - y^2
xx <- c(-1, 1); yy <- c(-1, 1)
## Not run:

for (xs in seq(-1, 1, by = 0.25)) {
    sol <- rk4(f, -1, 1, xs, 100)
        lines(sol$x, sol$y, col="darkgreen")
}
grid()
## End(Not run)</pre>
```

378 whittaker

|--|

#### **Description**

Smoothing of time series using the Whittaker-Henderson approach.

#### Usage

```
whittaker(y, lambda = 1600, d = 2)
```

#### **Arguments**

y signal to be smoothed.

lambda smoothing parameter (rough 50..1e4 smooth); the default value of 1600 has been

recommended in the literature.

d order of differences in penalty (generally 2)

#### **Details**

The Whittaker smoother family was first presented by Whittaker in 1923 for life tables, based on penalized least squares. These ideas were revived by Paul Eilers, Leiden University, in 2003. This approach is also known as Whittaker-Henderson smoothing.

The smoother attempts to both fit a curve that represents the raw data, but is penalized if subsequent points vary too much. Mathematically it is a large, but sparse optimization problem that can be expressed in a few lines of Matlab or R code.

#### Value

A smoothed time series.

#### Note

This is a version that avoids package 'SparseM'.

#### Author(s)

An R version, based on Matlab code by P. Eilers in 2002, has been published by Nicholas Lewin-Koh on the R-help mailing list in Feb. 2004, and in private communication to the author of this package.

wilkinson

wilkinson Matrix

# Description

Generate the Wilkinson matrix of size  $n \times n$ . The Wilkinson matrix for testing eigenvalue computations

# Usage

```
wilkinson(n)
```

#### **Arguments**

n

integer

# Details

The Wilkinson matrix for testing eigenvalue computations is a symmetric matrix with three non-zero diagonals and with several pairs of nearly equal eigenvalues.

#### Value

```
matrix of size n x n
```

#### Note

The two largest eigenvalues of wilkinson(21) agree to 14, but not 15 decimal places.

zeta

Riemann Zeta Function

# Description

Riemann's zeta function valid in the entire complex plane.

## Usage

zeta(z)

## **Arguments**

Z

Real or complex number or a numeric or complex vector.

# **Details**

Computes the zeta function for complex arguments using a series expansion for Dirichlet's eta function.

Accuracy is about 7 significant digits for abs(z)<50, drops off with higher absolute values.

#### Value

Returns a complex vector of function values.
